Supplementary Fig. 1. Definition of colonisation episodes. Colonisation episodes were assumed to start after either first detection or re-acquisition of a serotype and cleared when two consecutive culture-negative sample for the serotype were found for samples collected from week 1 to 27 from birth, while for samples collected after week 27 clearance was considered to have occurred when a single culture-negative sample for the serotype was detected.

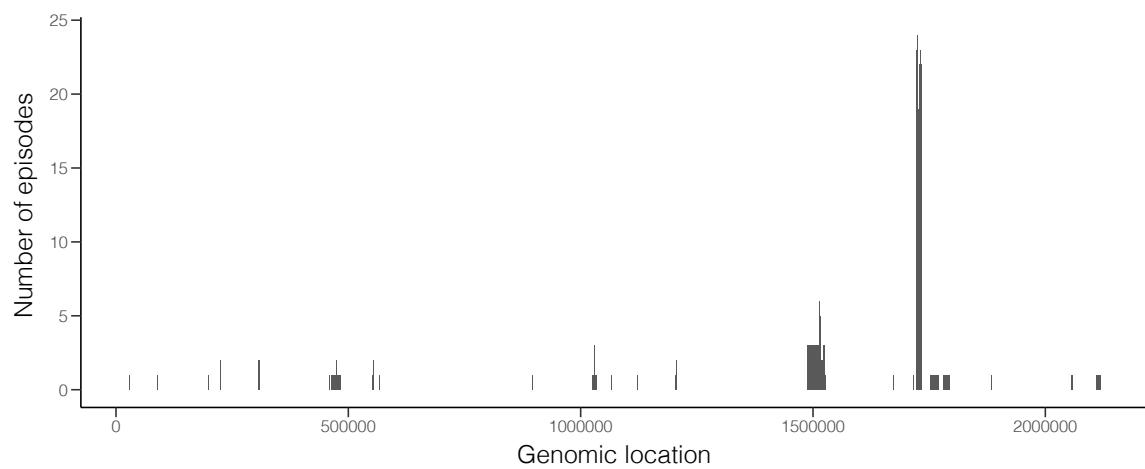

Supplementary Fig. 2. Within-host genetic diversity during natural colonisation. The strip charts show the number of SNPs calculated between isolates of the same serotype and ST within the same episode. The isolates sampled at 2, 4, 6 and 8 weeks from birth of an infant. The Y-axis of each plot is shown in \log_{10} scale for clarity.

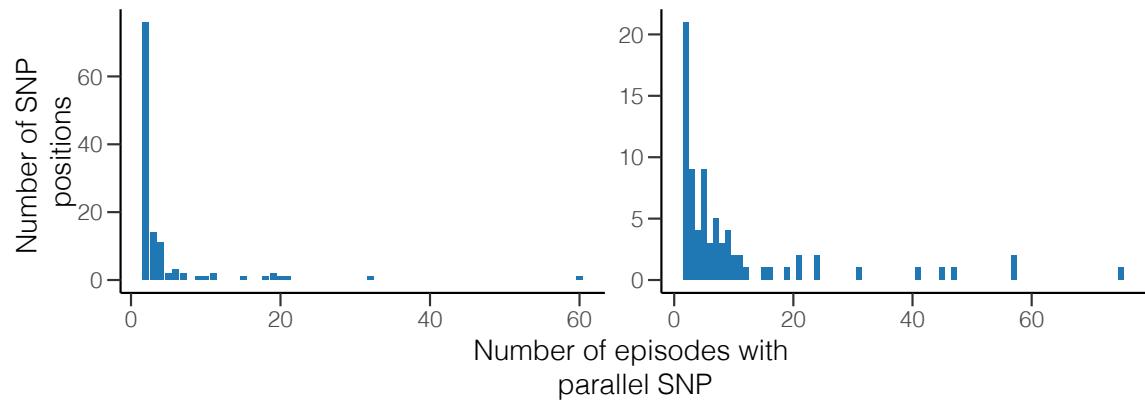

Supplementary Fig. 3. Within-host homologous recombination during natural colonisation.

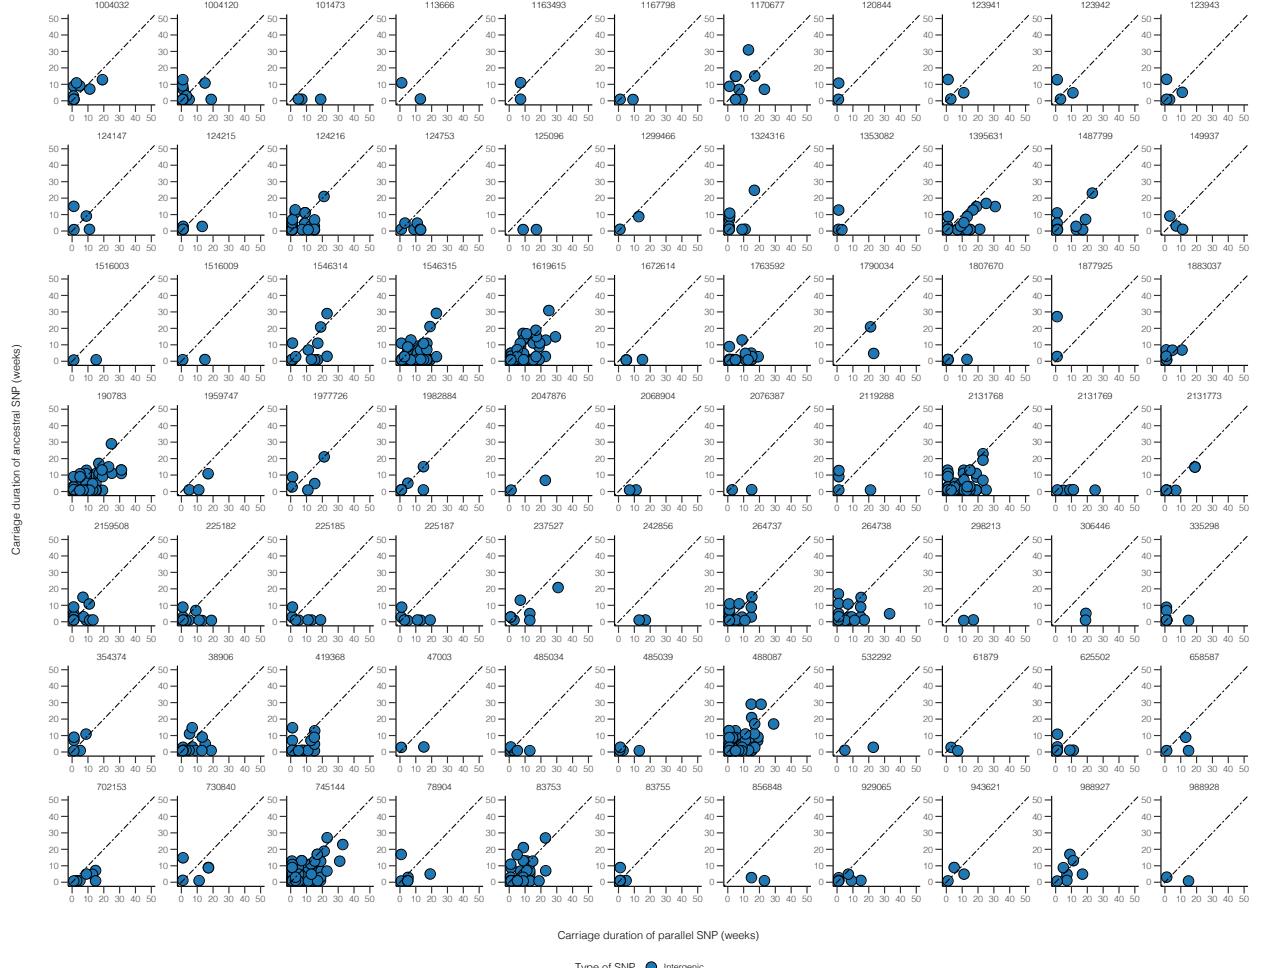

Panels (a-c) shows three examples of colonisation episodes where recombination events were detected. The episode name is shown in the format A:B:C where A, B and C represents the infant ID, serotype and number of episodes with the serotype respectively. (I) Colonisation episode showing the time points at which the serotype in the episode was detected. (II) Distribution of SNPs across genome. The coloured line (red) shows occurrence of a SNP in the strain using the first sequenced genome in the episode as the reference or ancestral strain. The SNPs are enhanced for clarity. (III) A multiple sequence alignment of showing location of the SNPs and visual evidence of the emergence of a recombinant strain within the episode. The value for r/m represents the number of SNPs within recombination blocks relative to SNPs outside the blocks. (IV) The distribution of the SNPs is highlighted by the frequency polygon, generated using widow size of 1000bp, which shows spikes in the SNP density across the recombinogenic regions.

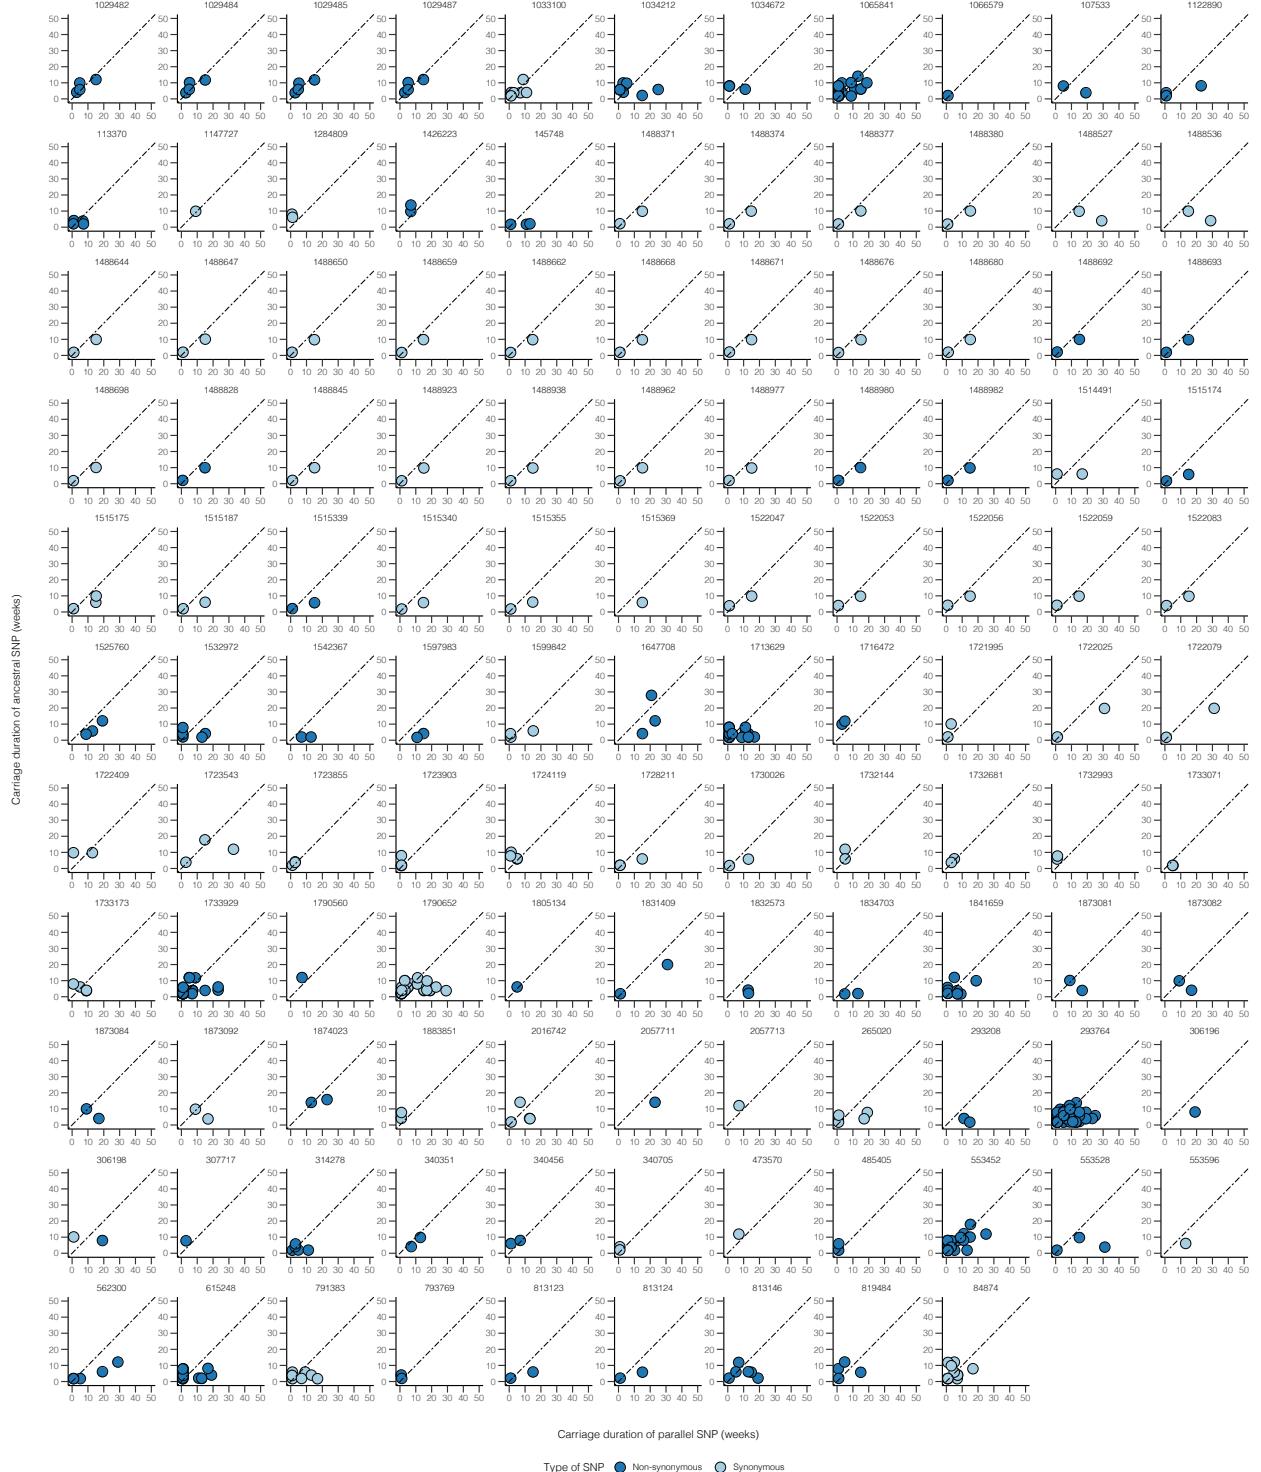

Supplementary Fig. 4. Hotspots of within-host recombination during natural colonisation. Maximum number of unique overlapping recombination events detected in different colonisation episodes are shown on the y-axis while the x-axis represent the position in the reference pneumococcal genome ATCC700669 (GenBank accession: NC_011900).

Supplementary Fig. 5. Histogram showing the distribution of parallel SNPs in genic and intergenic regions.

Supplementary Fig. 6. Scatter plots showing duration of carriage for the ancestral and parallel SNPs detected in intergenic regions during natural colonisation.

Supplementary Fig. 7. Scatter plots showing duration of carriage for the ancestral and parallel SNPs detected in genic regions during natural colonisation.
