Appendix 2.2

A2.2.1 Taxonomic and geographic coverage

Estimates of hydrological bioclimatic habitat position and range were generated for a total of 564 species. The number of species represented in each terrestrial bromeliad genus, and the proportion of species in each of these genera represented, is displayed in Table A2.2.1. There was no discernible taxonomic bias in terms of percentage genus coverage at the subfamilial level (AOV: $F = 0.365$, $p = 0.892$).

Group	Genus	Species sampled/Total species	Percentage genus coverage (%)
Pitcairnioideae	<i>Deuterocohnia</i>	10/18	55.6
	<i>Dyckia</i>	51/150	34.7
	<i>Encholirium</i>	18/26	69.2

	<i>Sequencia</i>	1/1	100.0
	<i>Steyerbromelia</i>	3/6	50.0
Brocchinioideae	<i>Brocchinia</i>	8/21	38.1
Terrestrial Bromeliaceae		564/1335	42.0

Table A2.2.1. Extent of taxon sampling by genus and subfamily.

Fig. A2.2.1. Geographic distribution of presence data for 564 species analysed in this investigation, plotted by taxonomic group.

The geographic coverage of the data analysed in this investigation is displayed in Fig. A2.2.1. Even when assessed at a very coarse scale, there was wide variation in the density of presence data between different geographical regions, with notably low densities in parts of Amazonia, the Caribbean islands, and the Central Andes.

A2.2.2 Relationships between univariate habitat ranges and number of presence points per species

The effect of the number of presence points on univariate habitat ranges was assessed across the entire dataset. Table A2.2.2 shows that across all species there were statistically significant positive correlations between the number of available presence points and the range of values observed for each bioclimatic variable, implying that species with few presence points tended to show narrower habitat ranges. Assuming this is not the result of under-recording, this might suggest that rarity is associated with narrow habitat ranges.

Bioclimatic variable range	Correlation with <i>n</i>		
	Slope	<i>r</i>²	<i>p</i>
Mean annual precipitation, MAP	0.75	28.68	< 0.001
Precipitation seasonality, P _{seas}	0.76	34.37	< 0.001
Precipitation of driest month, P _{dry}	0.85	26.54	< 0.001
Aridity index, AI	0.72	29.31	< 0.001
Ratio of actual to potential evapotranspiration, AET/PET	0.61	20.79	< 0.001

Table A2.2.2. Relationships between sample size and calculated ranges for bioclimatic variables across all species (*n* = 564).

A2.2.3 Relationships between bioclimatic variables

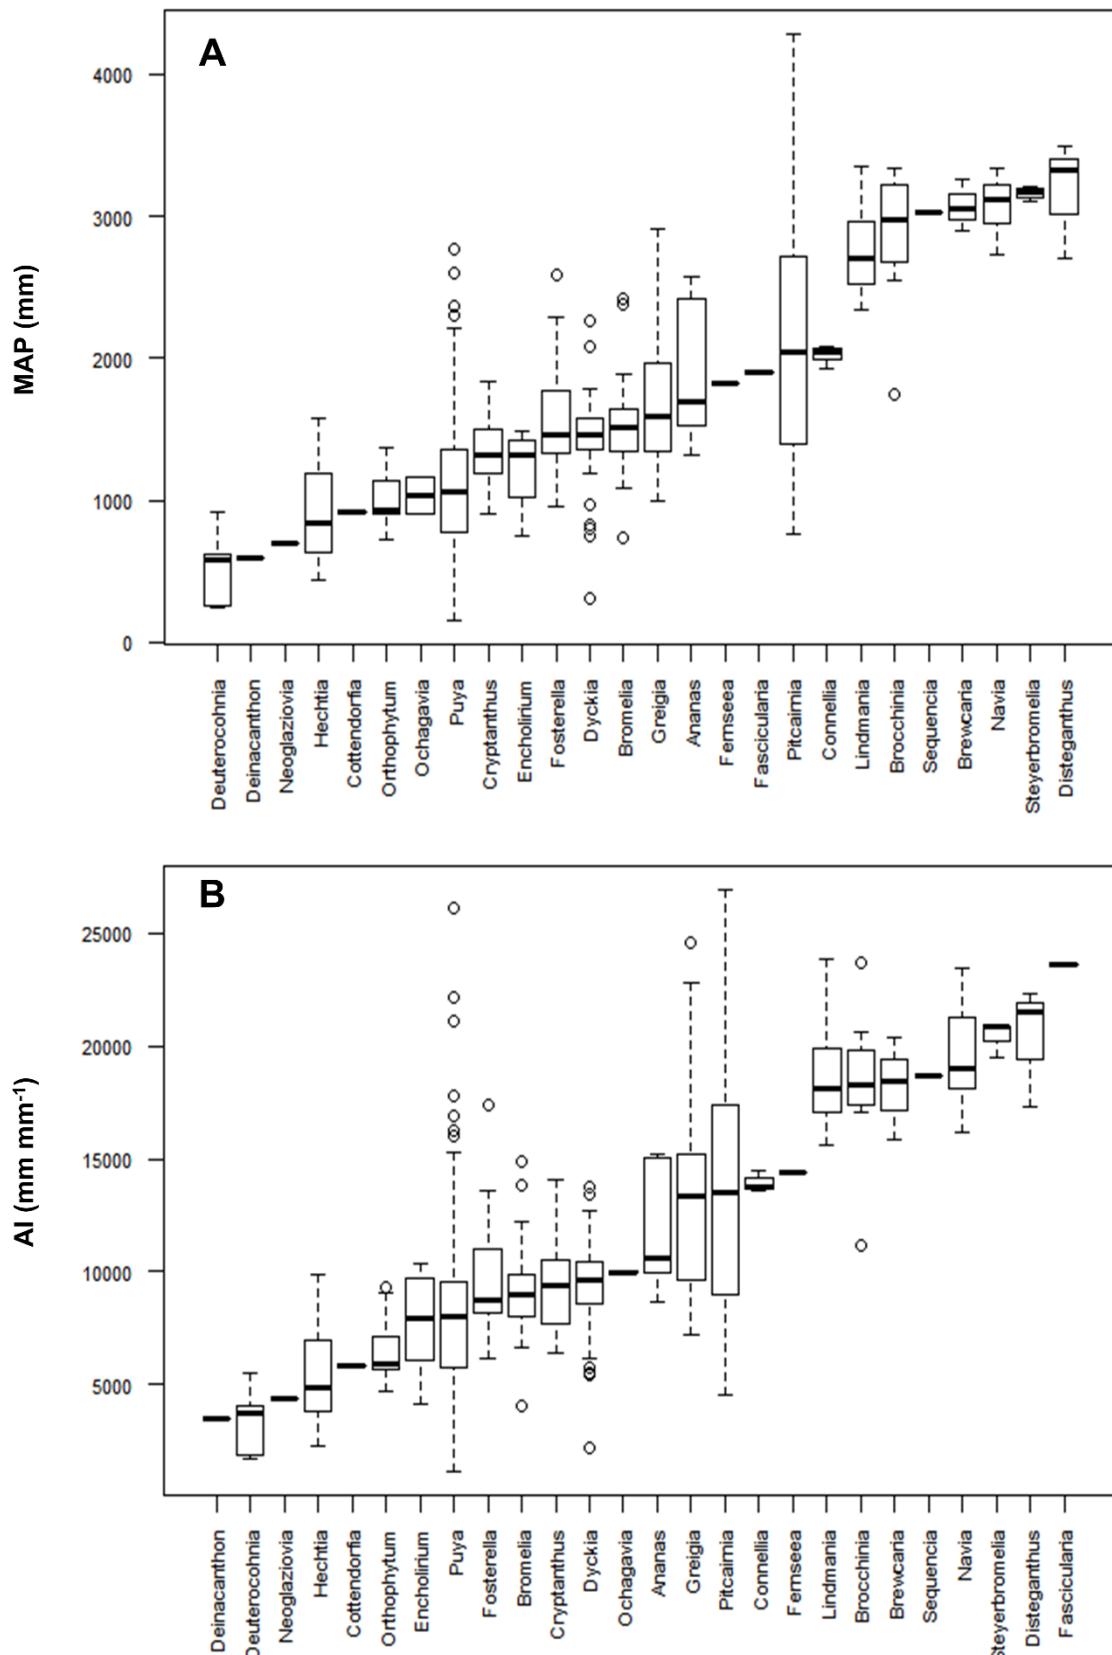

Pairwise linear regression was performed between mean univariate habitat position scores for all genera to assess the degree of collinearity. All pairs showed strong, statistically significant correlations, summarised in Table 2.3.3. Of all the variables, P_{seas} was the most weakly coordinated with other variables, as was borne out in PCA-based estimation of multivariate hydrological habitat position and range. This suggests that variation in overall moisture requirement could be partly decoupled from variation in tolerance of environmental seasonality.

	AI	MAP	P_{dry}	P_{seas}
AET/PET	+ , $r^2 = 77.19$, $p < 0.001$	+ , $r^2 = 79.81$, $p < 0.001$	+ , $r^2 = 71.54$, $p < 0.001$	- , $r^2 = 69.08$, $p < 0.001$
AI		+ , $r^2 = 82.89$, $p < 0.001$	+ , $r^2 = 74.89$, $p < 0.001$	- , $r^2 = 48.54$, $p < 0.001$
MAP			+ , $r^2 = 88.83$, $p < 0.001$	- , $r^2 = 61.21$, $p < 0.001$
P_{dry}				- , $r^2 = 71.58$, $p < 0.001$

Table A2.2.3. Pairwise correlations between genus-mean scores for bioclimatic indices (aridity index, AI; mean annual precipitation, MAP; precipitation of driest month, P_{dry}; precipitation seasonality, P_{seas}).

Appendix 2.3

A2.3.1 Variation in hydrological habitat position and range by genus

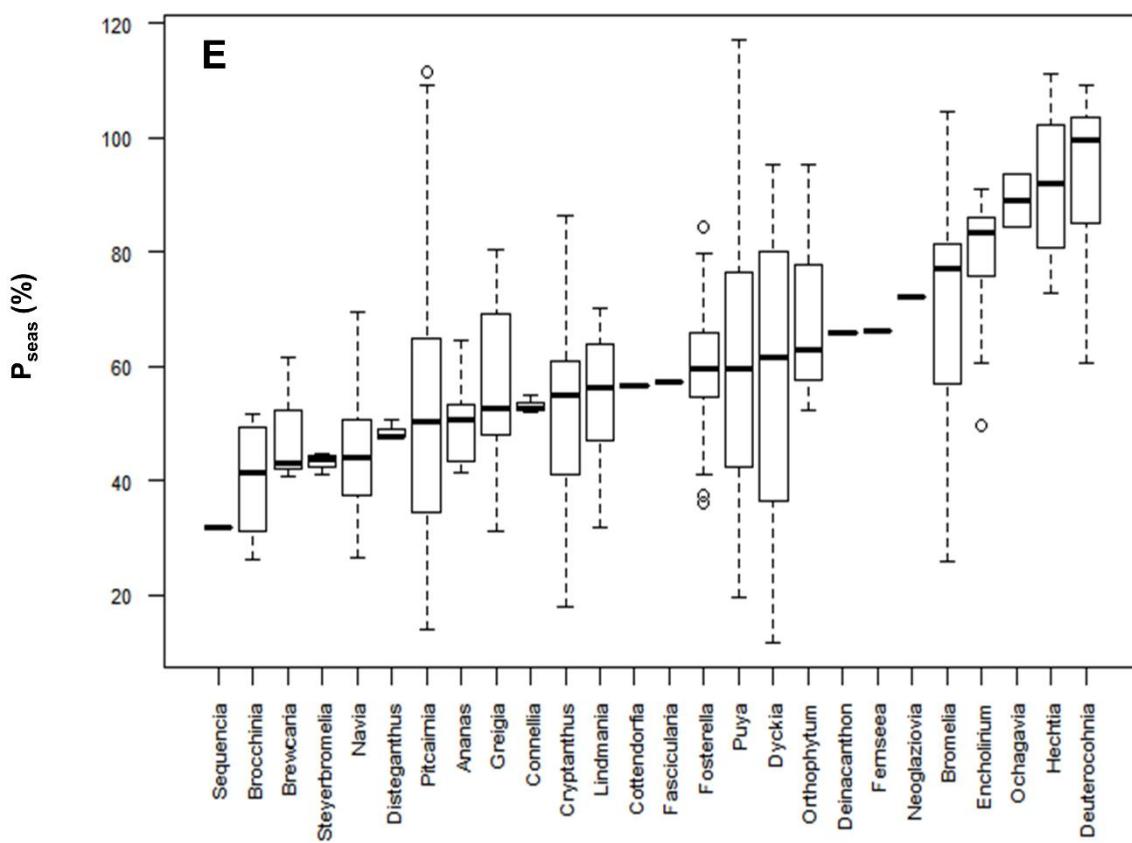

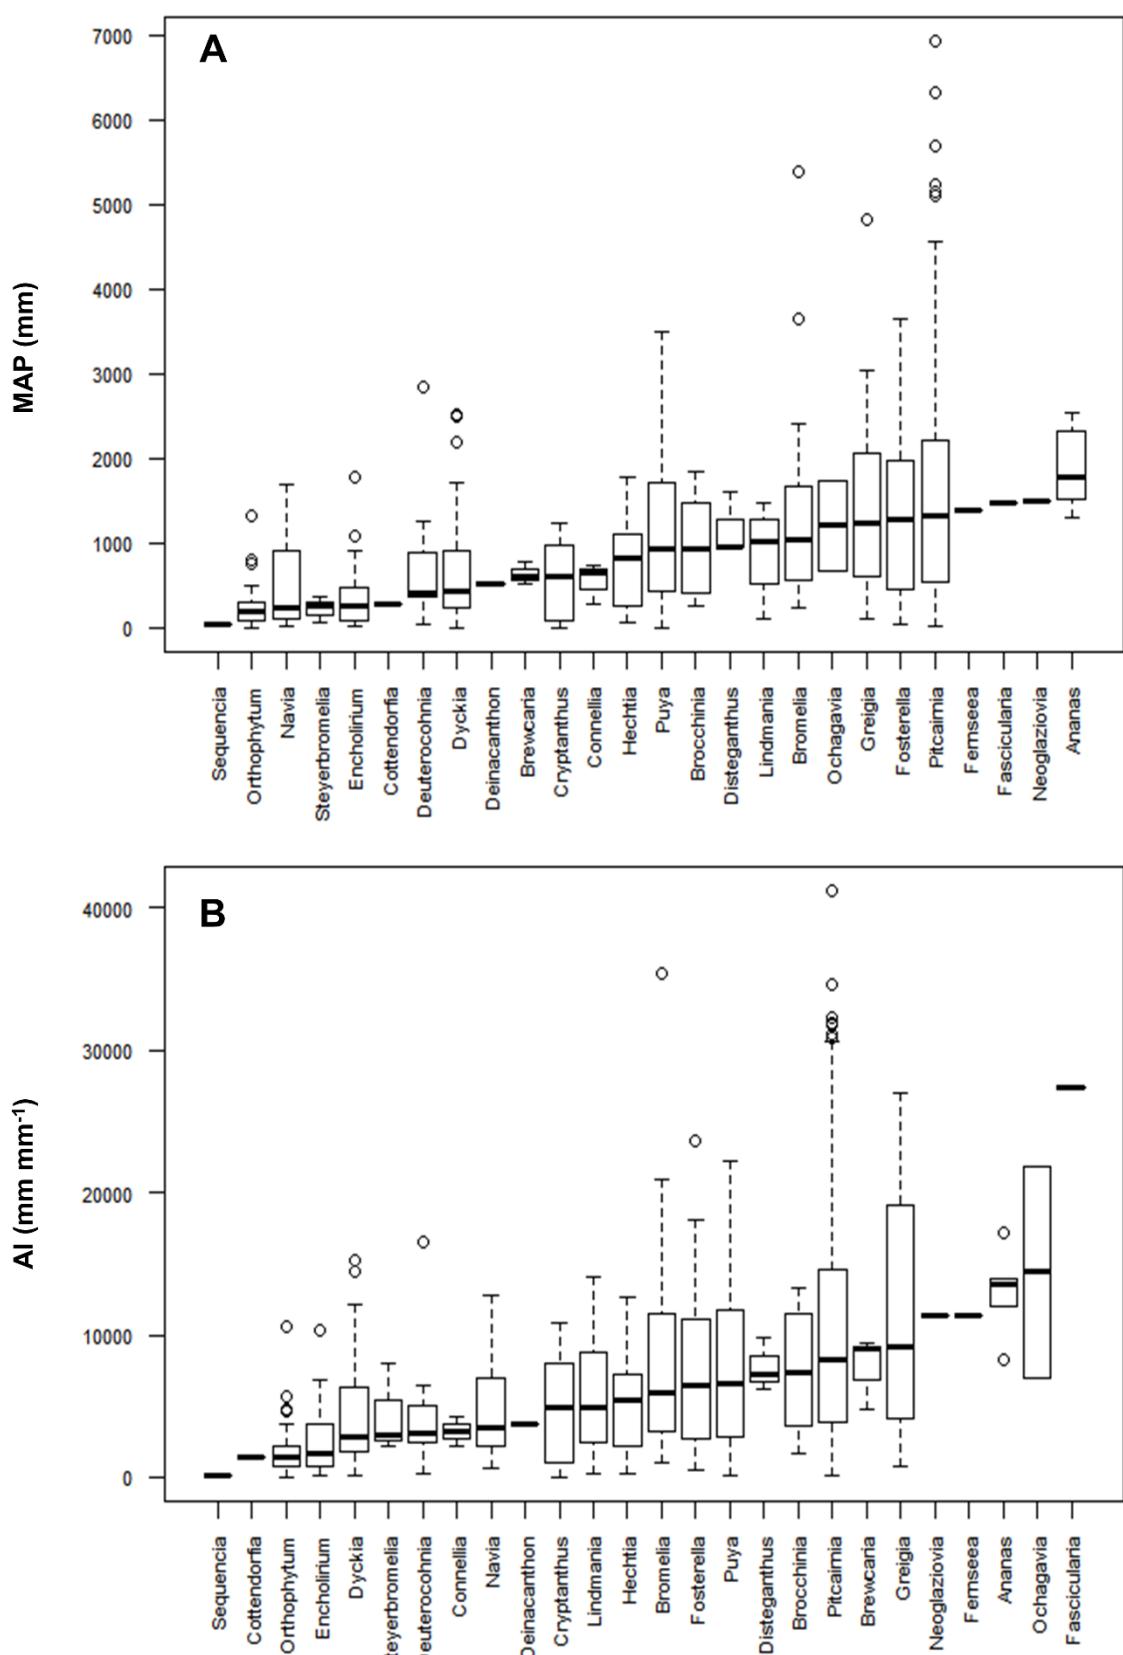

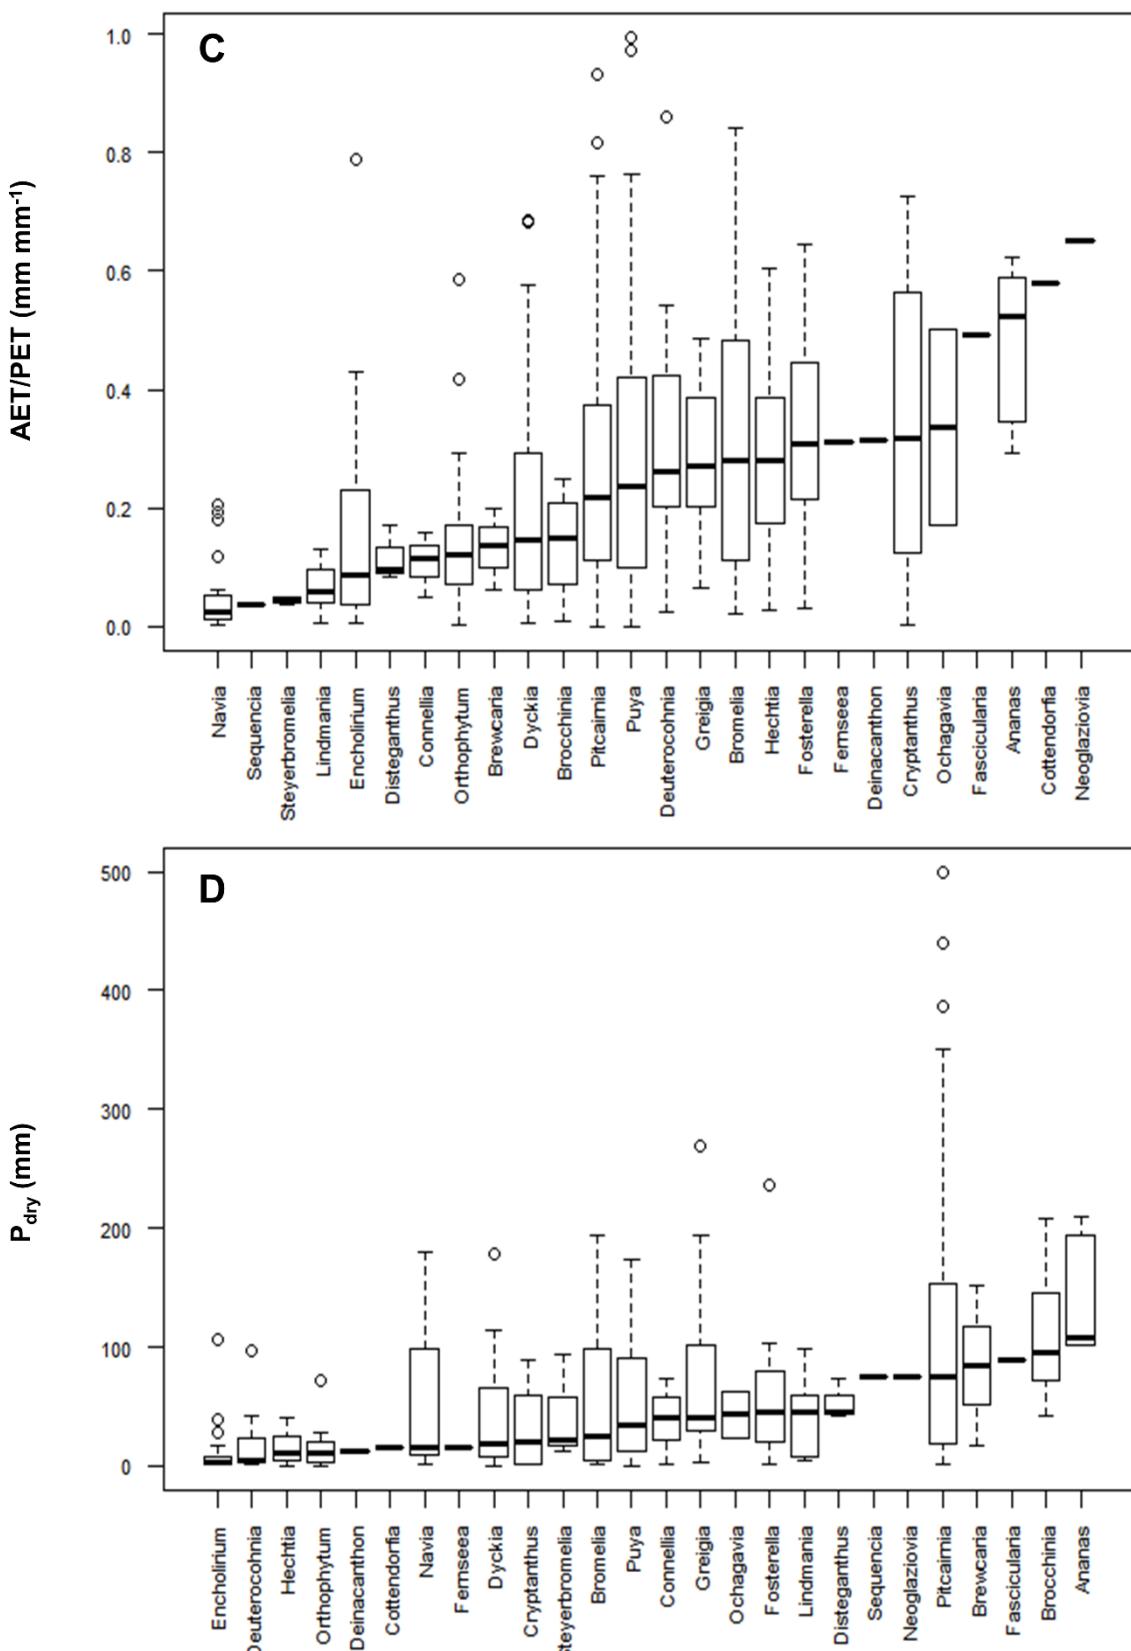

Figure A2.3.1. Terrestrial bromeliad genera ranked by median score for species' mean values for five bioclimatic variables: b) MAP; B) AI; c) AET/PET; d) P_{dry} ; e) P_{seas} . Boxes show median values and interquartile range (IQR), with whiskers of length (1.5 x IQR) and outliers plotted as individual points.

Variation in mean scores for habitat position is shown by genus median in Fig. A2.3.1. Median MAP score was lowest in *Deuterocohnia*, followed by *Deinacanthon*, *Neoglaziovia* and *Hechtia*. The same four genera occupied these positions in terms of both median scores for AI and AET/PET.

Deuterocohnia, *Deinacanthon*, *Neoglaziovia* and *Encholirium* were the four genera with lowest median scores for species' mean scores for P_{dry} . *Deuterocohnia* and *Hechtia* showed the highest median scores for P_{seas} , followed by *Ochagavia* and *Encholirium*. At the other end of the spectrum, the highest median scores for AET/PET occurred in *Sequencia*, *Steyerbromelia*, *Navia* and *Brocchinia*. The same genera showed the four lowest median scores for P_{seas} and the highest for P_{dry} . By contrast, the four highest-scoring genera for AI were *Fascicularia*, *Steyerbromelia*, *Disteganthus* and *Navia*, and the highest median scores for MAP occurred in *Disteganthus*, *Steyerbromelia*, *Navia* and *Brewcaria*.

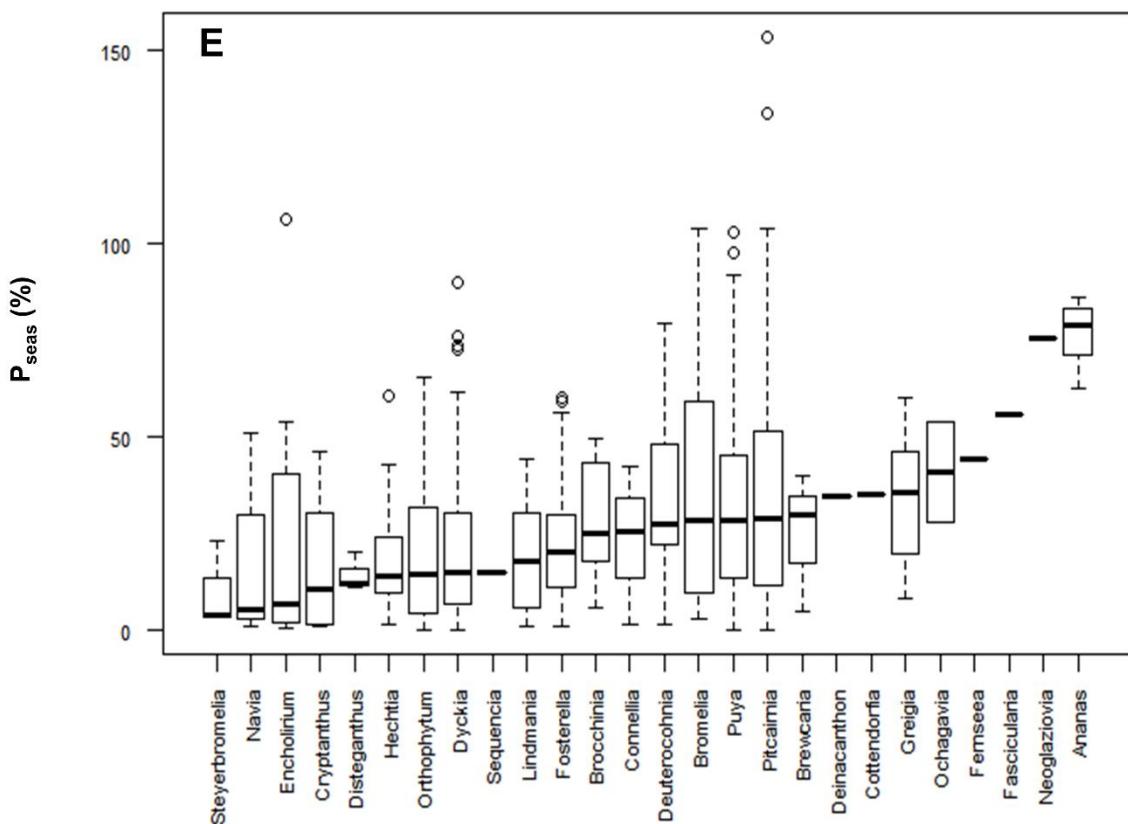

Figure A2.3.2. Terrestrial bromeliad genera ranked by median score for species' ranges of values for five bioclimatic variables: a) MAP; b) AI; c) AET/PET; d) P_{dry} ; e) P_{seas} . Boxes show median values and interquartile range (IQR), with whiskers of length (1.5 x IQR) and outliers plotted as individual points.

Fig. A2.3.2 shows variation in habitat range by genus median. In terms of MAP, the narrowest ranges occurred in *Sequencia*, *Orthophytum* and *Navia*, while the widest occurred in *Ananas*, *Neoglaziovia* and *Fascicularia*. This pattern was broadly consistent with the results for AI, in which the monospecific *Cottendorfia* displayed a notably narrow range. However, this contrasted with the broad range shown by *Cottendorfia* in terms of AET/PET. Otherwise, rankings for AET/PET were again rather similar. The narrowest ranges in terms of P_{dry} occurred in strongly xeromorphic CAM terrestrial genera including *Encholirium*, *Deuterocohnia* and *Hechtia*, while the genera *Brocchinia* and *Brewcaria* ranked surprisingly highly, alongside *Ananas* and *Fascicularia*. The pattern for P_{seas} was similar to that observed for MAP.

Appendix 2.4

A2.4.1 Variation in hydrological habitat and position within taxonomic groups

PCA was performed separately on data for species within each major taxonomic group in order to identify more detailed, lineage-specific trends in variation in hydrological habitat mean and range.

Brocchinoideae and Lindmanioideae

Among the Brocchinoideae and Lindmanioideae, the overall moisture vs. seasonality distinction was maintained, and the most distinctive hydrological habitat means occurred in *Connellia* (Lindmanioideae), which clustered tightly in the area of the PC1-PC2 climate space characterised by lower overall moisture and moderate seasonality (Fig. A2.4.1). Scores for *Brocchinia* (Brocchinoideae) and *Lindmania* (Lindmanioideae) species covered wider habitat ranges, with the centre of the range for *Lindmania* spp. being located further towards the high-seasonality end of the climate space than for *Brocchinia* spp. The *Lindmania* species whose hydrological habitat mean was associated with the highest level of seasonality was *L. thyrsoides* L.B.Sm., while *L. nubigena* (L.B.Sm.) L.B.Sm. occupied the other end of this spectrum. In *Brocchinia*, a shorter gradient existed between *B. reducta* Baker and *B. delicatula* L.B.Sm., the latter being associated with the lowest levels of seasonality. Meanwhile the habitat mean of *B. rupestris* (Gleason) Holst was associated with considerably lower overall moisture than any other species in the genus or in Lindmanioideae.

PCA on hydrological habitat range data for Brocchinoideae and Lindmanioideae identified two axes of variation corresponding to overall environmental moisture (MAP, AI, AET/PET) and seasonality (P_{dry} , P_{seas} ; Fig. A2.4.2). In *Brocchinia*, the broadest habitat ranges occurred in *B. hechtiioides* Mez and *B. tatei* L.B.Sm., two tank-forming species. *B. delicatula* showed narrow habitat range with respect to seasonality but not total moisture, while the reverse was true for *B. rupestris*. Among *Lindmania* species, broad habitat range occurred in species such as the strongly morphologically-reduced *L. subsimplex* L.B.Sm.. Narrow habitat range in terms of seasonality but not total moisture occurred in *L. thyrsoides*, with the reverse being true for *L. nubigena*. Most *Connellia* species showed relatively broad habitat ranges, the exception being *C. caricifolia* L.B.Sm., which appeared to be strongly restricted by seasonality.

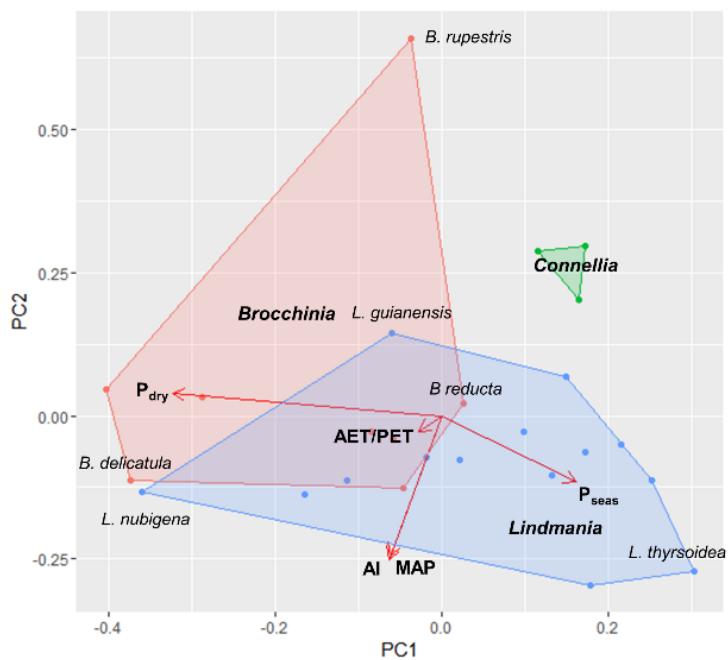

Figure A2.4.1. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Brocchinioideae and Lindmanioideae ($n = 35$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

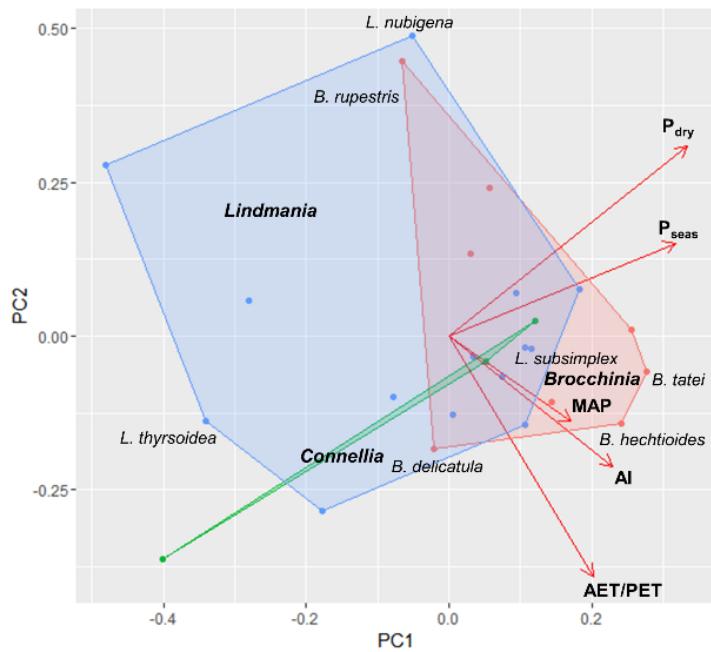

Figure A2.4.2. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Brocchinioideae and Lindmanioideae ($n = 35$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Hechtia (Hechtioideae)

In the Central-North American succulent CAM genus *Hechtia* (Hechtioideae) there was approximately equal variation across total moisture and seasonality axes (Fig. A2.4.3). Species such as *H. texensis* S.Watson occupied the area of climate space characterised by moderate seasonality and low overall moisture, while strongly seasonal environments with high overall moisture were associated with species including *H. laevis* L.B.Sm. The two species whose habitat means were located in the region of climate space characterised by the highest moisture and lowest seasonality were *H. lundelliorum* L.B.Sm. and *H. tillandsioides* (André) L.B.Sm., both of which are relatively thin-leaved and lack prominent spines.

PCA of habitat range data for *Hechtia* identified two axes of variation corresponding to overall moisture (including P_{dry}) and P_{seas} (Fig. A2.4.4). The broadest overall habitat range occurred in *H. glomerata* Zucc., while *H. stenopetala* Klotzsch showed higher habitat range in terms of overall moisture but not seasonality. *H. lyman-smithii* Burt-Utley & Utley appeared to be limited by seasonality more than by overall moisture, while the reverse was true of *H. liebmannii* Mez. *H. pedicellata* S.Watson appeared to be equally restricted by both factors.

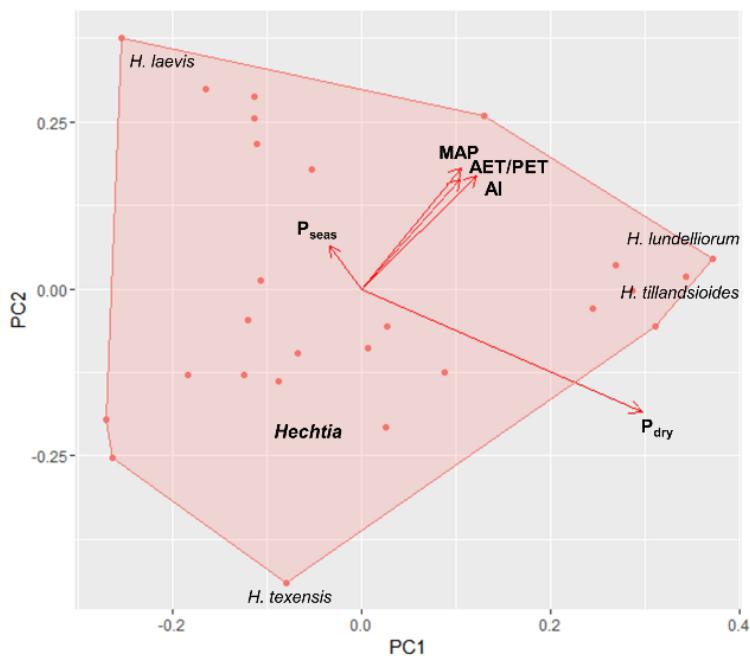

Figure A2.4.3. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Hechtioideae ($n = 26$). Convex hull covers all species. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

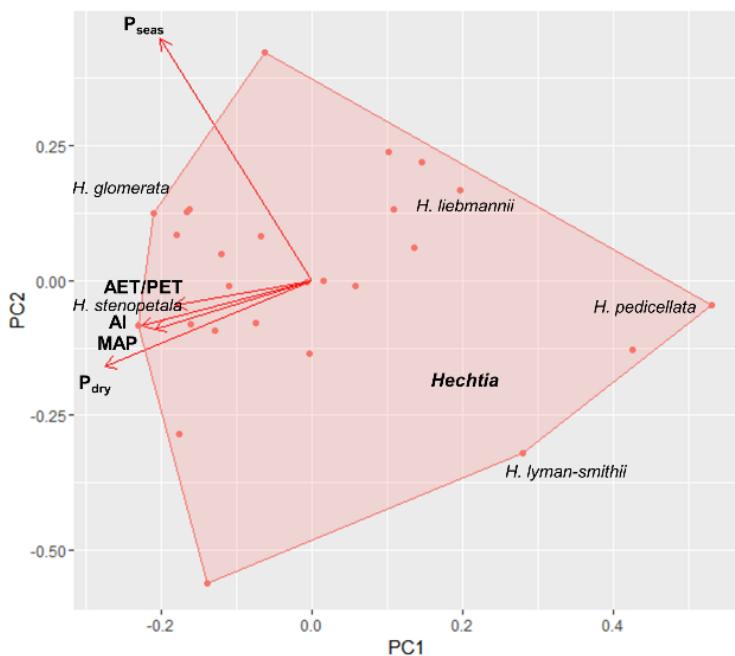

Figure A2.4.4. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Hechtioideae ($n = 26$). Convex hull covers all species. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Navioideae

The results of PCA on hydrological habitat mean data for the Navioideae were consistent with the overall moisture vs. seasonality distinction. In terms of variation in species' scores, the strongest contrast was between the monospecific genus *Cottendorfia* and the remainder of the subfamily (Fig. A2.4.5). *C. florida* was located in the corner of the PC1-PC2 climate space associated with the lowest overall moisture and moderate seasonality. *Navia* spp. showed the widest range of habitat means, and this variation was primarily parallel to the PC loading for seasonality, suggesting that overall moisture demand is relatively strongly conserved across the genus. Species associated with the highest levels of seasonality included *N. ovoidea* L.B.Sm., Steyerl. & H.Rob., while species such as *N. terramarae* L.B.Sm. & Steyerl. occupying the other end of the spectrum. The area of climate space occupied by *Brewcaria* spp. fell towards the centre of that occupied by *Navia* spp., and variation in habitat mean in *Brewcaria* was again confined to the seasonality axis. While data were available for only three *Steyerbromelia* species, these seemed to conform to the same pattern, and their habitat means were also located towards the centre of the range occupied by *Navia* spp. *Sequencia serrata* (L.B.Sm.) Givnish, the sole representative of its genus, was located towards the low-seasonality end of the area of climate space occupied by *Navia* spp. Overall, it appears that moisture requirement is

relatively strongly conserved across the Navioideae, with the exception of *C. florida*, while there has been some degree of adaptation to different temporal distribution of precipitation.

When PCA was performed on habitat range data for Navioideae species, bioclimatic variable loadings fell onto three axes: 1) MAP and AI; 2) P_{dry} and P_{seas} ; 3) AET/PET (Fig. A2.4.6). The first and second of these axes were orthogonal, with the third lying approximately midway between. The broadest habitat ranges occurred in *Navia* spp., notably the diminutive *N. duidae* L.B.Sm. Narrow habitat range with respect to total moisture but not seasonality occurred in *N. luzuloides* L.B.Sm., Steyerl. & H.Rob., whereas the converse arrangement was true for *N. terramarae*. Habitat ranges of *Brewcaria*, *Cottendorfia* and *Steyerbromelia* species fell within the range of habitat ranges occupied by *Navia* spp., whereas *Sequencia serrata* displayed exceptional specificity with respect to overall moisture.

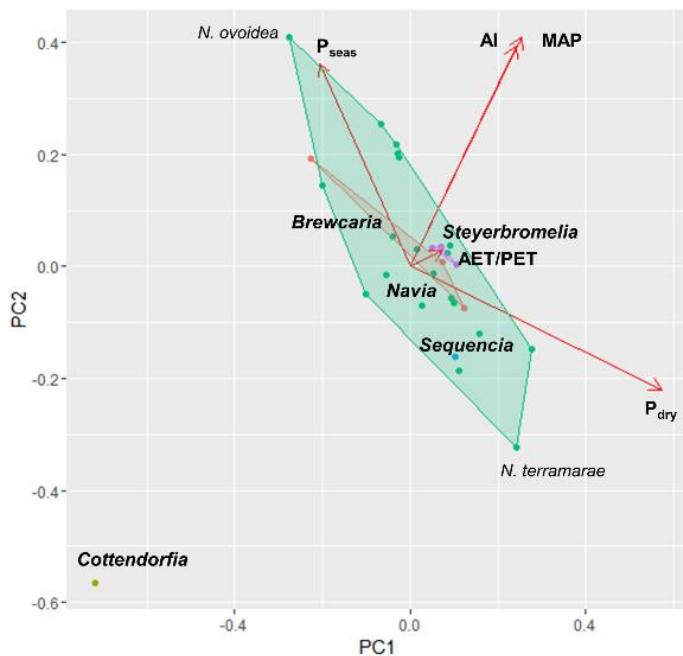

Figure A2.4.5. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Navioideae ($n = 28$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

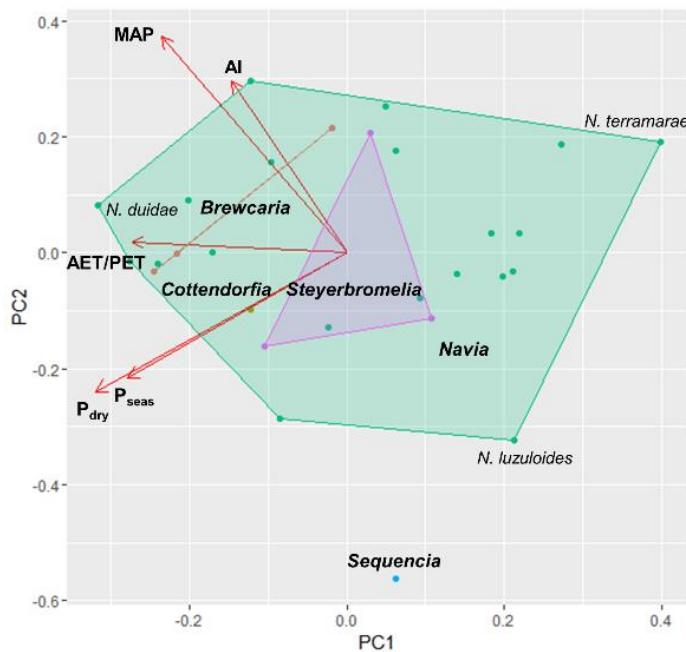

Figure A2.4.6. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Navioideae ($n = 28$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Pitcairnia and *Fosterella*

Hydrological habitat means in the large genus *Pitcairnia* varied widely across the PC1-PC2 climate space, where the total moisture vs. precipitation seasonality distinction was supported (Fig. A2.4.7). Aseasonal, high-moisture environments were associated with broad-leaved, often petiolate species such as *P. archeri* L.B.Sm., while strongly seasonal environments with high overall moisture hosted species such as the largely coastal *P. calcicola* J.R.Grant & J.F.Morales. Seasonal low-moisture environments were associated with species with morphologically-reduced leaves, such as *P. micheliana* Andrews, while aseasonal low-moisture environments were occupied by species such as *P. nobilis* Mez & Sodiro. The range of habitat means of *Fosterella* spp. fell within the core of the range occupied by *Pitcairnia* spp. *Fosterella* spp. showed slightly more dispersion along the overall moisture axis than the seasonality axis. The habitat mean of the narrow-leaved South American lithophyte *F. albicans* (Griseb.) L.B.Sm. was located in the lowest-moisture and most seasonal corner of the climate space occupied by *Fosterella* spp. Seasonal, high-moisture environments were associated with the broad-leaved Central American species *F. micrantha* (Lindl.) L.B.Sm., while

aseasonal, high-moisture environments were occupied by the lowland Amazonian species *F. pearcei* (Baker) L.B.Sm.

When PCA was performed on habitat range data for *Pitcairnia* and *Fosterella*, the bioclimatic variable loadings fell into four groupings: 1) AET/PET; 2) P_{seas} ; 3) MAP and AI; 4) P_{dry} (Fig. A2.4.8). *Pitcairnia* spp. such as *P. heterophylla* (Lindl.) Beer and *P. macrantha* André showed some of the broadest habitat ranges, while other species appeared to be differentially sensitive to different bioclimatic variables. *P. mituensis* L.B.Sm. displayed a particularly narrow habitat range with respect to AET/PET, whereas *P. condorensis* Manzan. & W.Till. appeared to be most strongly limited by P_{seas} and *P. prolifera* Rauh by P_{dry} . Among *Fosterella* spp., the broadest habitat ranges occurred in species such as *F. pearcei*, while *F. caulescens* Rauh appeared to be limited by AET/PET and P_{seas} , and *F. vasquezii* E.Gross & Ibisch by MAP/AI and P_{dry} .

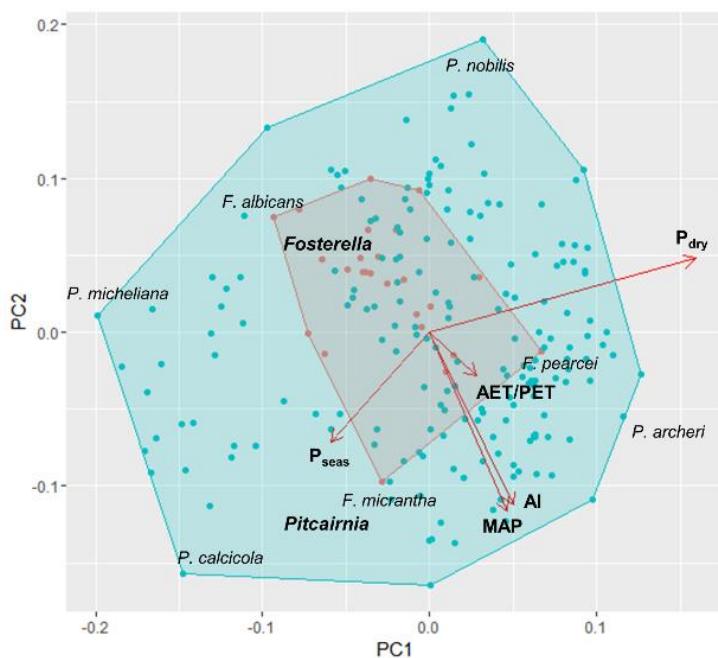

Figure A2.4.7. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for *Pitcairnia* and *Fosterella* ($n = 208$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

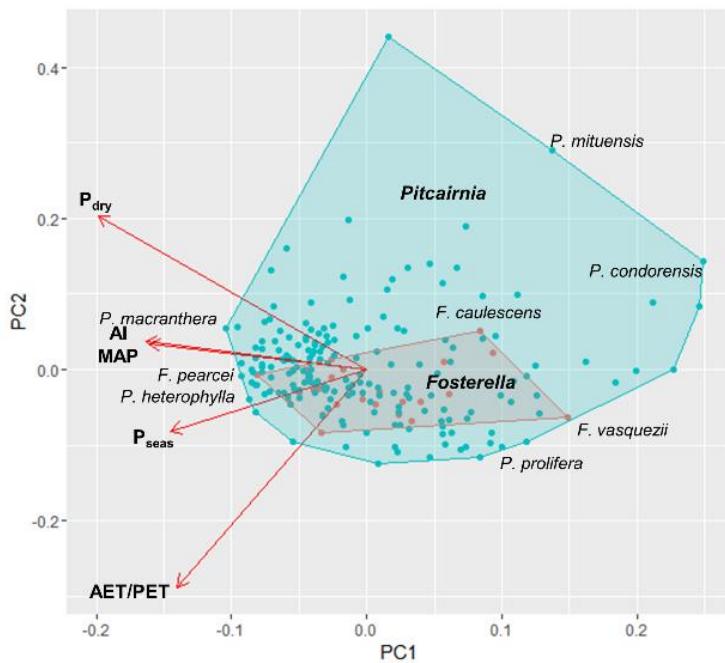

Figure A2.4.8. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for *Pitcairnia* and *Fosterella* ($n = 208$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Xeric Clade Pitcairnioideae

For the Xeric Clade Pitcairnioideae, the total moisture vs. precipitation seasonality distinction in bioclimatic variable loadings held true (Fig. A2.4.9). Species' scores for the three genera overlapped towards the centre of the PC1-PC2 climate space, but each genus also occupied more distinctive regions of the space. *Deuterocohnia* spp. occurred in the lowest moisture environments with moderate levels of seasonality. Species associated with the very driest regions included the miniaturised *De. haumanii* A.Cast. and *De. lorentziana* (Mez.) M.A.Spencer & L.B.Sm. Species with habitat means located in slightly higher-moisture and less seasonal areas of the climate space included *De. meziana* Kuntze ex Mez. *Dyckia* is the largest of the Xeric Clade genera and showed the widest range of hydrological habitat means. Two major loose clusters were identifiable: both towards the high-moisture end of the climate space, but towards opposite ends of the seasonality spectrum, reflecting the geographical distribution of *Dyckia* diversity in central and southern Brazil. From the first of these groups, the relatively large and broad-leaved *Dy. maritima* Baker was associated with the lowest levels of seasonality, while from the second group the highly spinose species *Dy. dawsonii* L.B.Sm. occurred in environments with the highest seasonality and highest

overall moisture. One exceptional *Dyckia* species, *Dy. velascana* Mez, occurred in an area of habitat space comparable to those occupied by *Deuterocohnia* spp. Finally, in the genus *Encholirium* most variation was along the seasonality axis, with a lesser amount of variation in overall moisture. The species *E. spectabile* Mart. ex Schult. & Schult.f. was associated with the driest and most aseasonal environments, while *E. longiflorum* Leme occupied the area of habitat space characterised by the most extreme seasonality but somewhat higher overall moisture.

Three groupings of bioclimatic variable loadings were identified when PCA was performed on habitat range data for Xeric Clade species: 1) MAP, AI and AET/PET; 2) P_{dry} ; 3) P_{seas} (Fig. A2.4.10). The first and second of these axes were orthogonal, with the third lying approximately midway between. There was extensive overlap in habitat ranges between species of each of the three Xeric Clade genera. In *Deuterocohnia*, the broadest habitat range occurred in the miniaturised *De. strobilifera* Mez. *De. brevifolia* (Griseb.) M.A.Spencer & L.B.Sm. appeared to be sensitive to P_{dry} but not overall moisture or P_{seas} , whereas the opposite was true for *De. seramisiana* R.Vásquez, Ibisch & E.Gross. The range of hydrological habitat range scores for *Dyckia* species was higher than for the other two genera, and the broadest habitat ranges occurred in species such as *Dy. pulquinensis* Wittm. *Dy. dawsonii* was strongly restricted by P_{dry} but not overall moisture or P_{seas} , while the reverse held for species such as *Dy. exserta* L.B.Sm. In *Encholirium*, the broadest habitat range occurred in *E. spectabile*. P_{dry} appeared to be more restrictive than either overall moisture or P_{seas} for *E. ctenophyllum* Forzza & Zappi, whereas the opposite was true for *E. biflorum* Mez (Forzza).

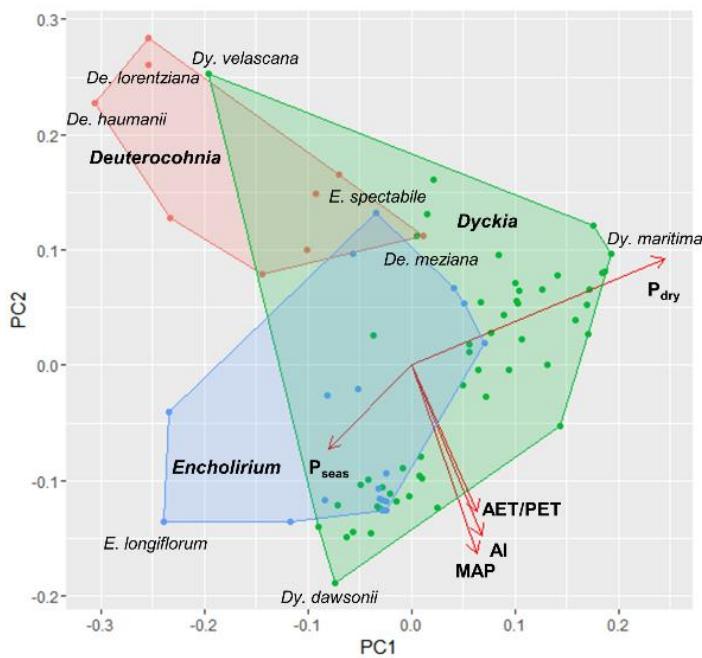

Figure A2.4.9. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Xeric Clade Pitcairnioideae ($n = 79$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

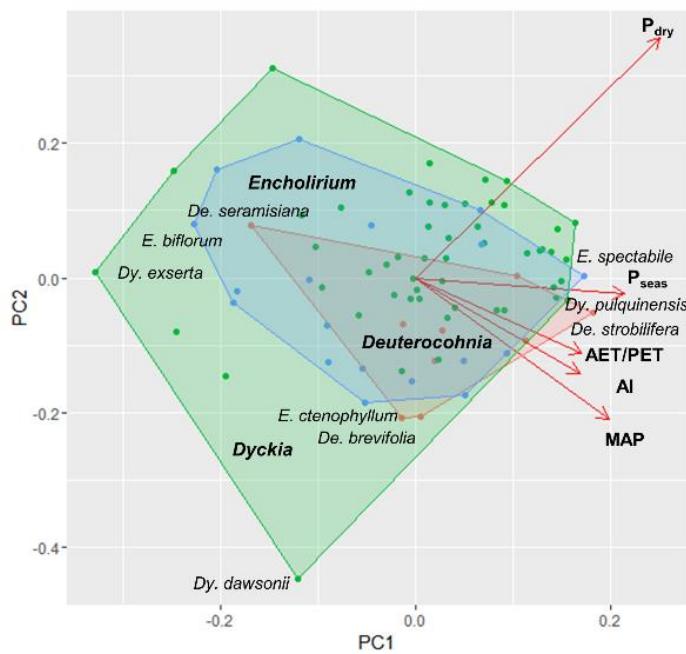

Figure A2.4.10. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Xeric Clade Pitcairnioideae ($n = 79$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Puya (Puyoideae)

PCA performed on habitat mean data for *Puya* revealed a different association between bioclimatic variables from that which was observed in all other taxonomic groups (Fig. A2.4.11). MAP, AI, and P_{dry} were all approximately aligned along one axis (corresponding to PC1), with P_{seas} also aligned in the opposite direction, while AET/PET alone formed an orthogonal axis (PC2). Most *Puya* spp. clustered relatively tightly in PC1-PC2 climate space, but some species occupied more extreme regions. The most aseasonal, high-moisture environments were occupied by *P. fulgens* L.B.Sm. from the Peruvian Amazon. The Colombian montane forest species *P. roldanii* Betancur & Callejas scored lowly on PC1, suggesting its association with high-moisture environments, but highly on PC2, indicative of low AET/PET. Meanwhile the Argentinian *P. harmsii* (A.Cast.) A.Cast. occurred in the most seasonal, low-moisture environments, and *P. volcanensis* A.Cast., from the same geographical region, showed a similar habitat mean except that it displayed a higher AET/PET score.

When habitat range data for *Puya* was subjected to PCA, two axes of variation were revealed, one corresponding to AET/PET and the other to all remaining bioclimatic variables (Fig. A2.4.12). One species showing particularly broad habitat range was *P. boliviensis* Baker. The Peruvian species *P. angusta* L.B.Sm. was more strongly restricted by AET/PET than by other factors, while the opposite was true of the Ecuadorean *P. sodiroana* Mez.

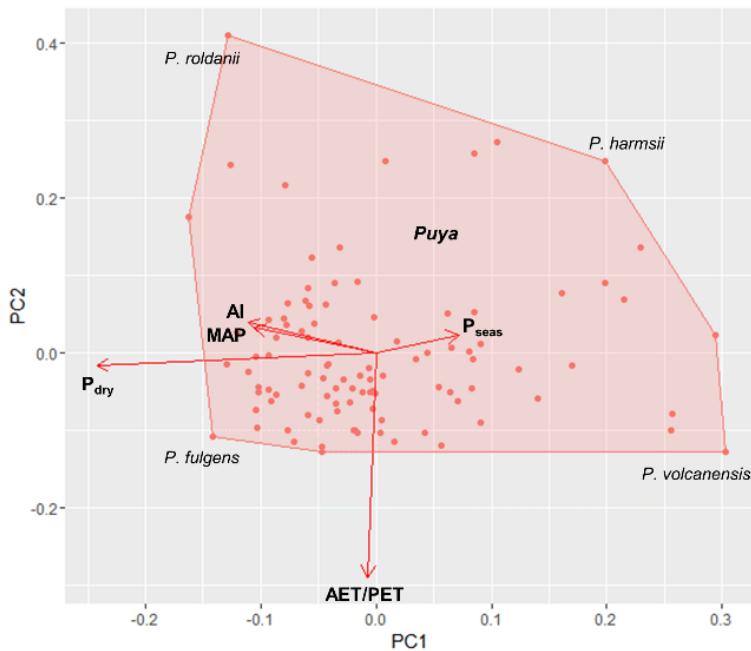

Figure A2.4.11. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Puyoideae ($n = 99$). Convex hull covers all species. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

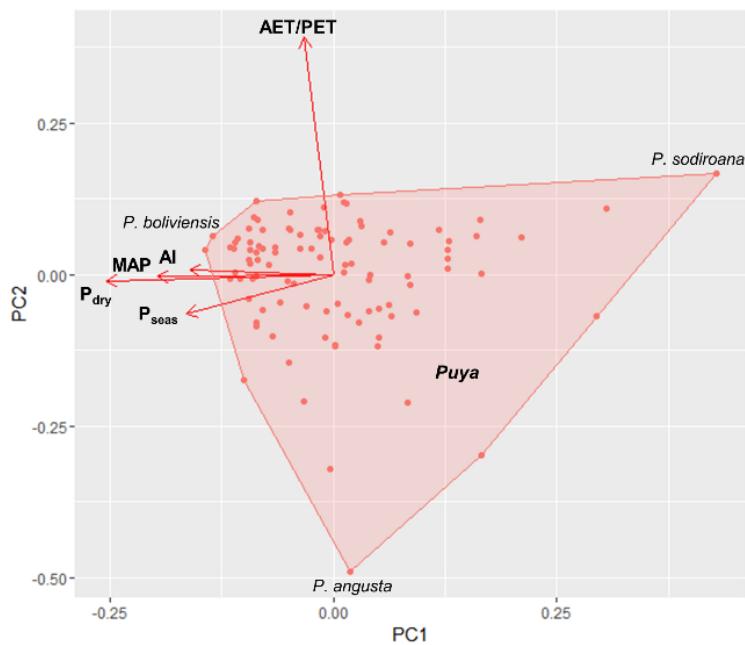

Figure A2.4.12. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for Puyoideae ($n = 99$). Convex hull covers all species. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

C₃ early-diverging Bromelioideae

PCA for habitat mean data for the four strictly C₃ genera of early-diverging Bromelioideae (*Fascicularia*, *Fernseea*, *Greigia* and *Ochagavia*) were broadly consistent with the overall moisture vs. seasonality distinction (Fig. A2.4.13). The largest of the four genera is *Greigia*. *Greigia* spp. hydrological habitat means varied roughly equally along the total moisture and seasonality axes. Andean species such as *G. sodiroana* Mez occupied the least seasonal but lowest overall moisture environments, while *G. kessleri* H.E.Luther occurred in more seasonal, low-moisture environments. Higher-moisture, seasonal environments were occupied by Central American species such as *G. rohwedera* L.B.Sm., while the species associated with the highest levels of overall moisture and moderate seasonality was *G. sylvicola* Standl. Habitat means of species of all other genera fell within the range occupied by *Greigia* spp. The monospecific Chilean genus *Fascicularia* was located in the high-moisture and moderately seasonal region of the climate space, while the single *Fernseea* species analysed was also associated with relatively high levels of moisture but stronger seasonality. Both Chilean *Ochagavia* species were associated with lower total moisture and strong seasonality.

PCA of habitat range data for C₃ early-diverging bromelioid genera identified two groups of aligned bioclimatic variable loadings corresponding to overall moisture and seasonality (Fig. A2.4.14). The broadest hydrological habitat ranges occurred in the Ecuadorean *Greigia sodiroana*. The Bolivian *G. kessleri* was more sensitive to seasonality than total moisture, with the opposite being true for the Venezuelan *G. alborosea* (Griseb.) Mez. Both *Fascicularia bicolor* (Ruiz & Pav.) Mez and *Ochagavia litoralis* (Phil.) Zizka, Trumper & Zöllner showed relatively broad habitat ranges, while that of *O. carnea* (Beer) L.B.Sm. & Looser was slightly narrower with respect to both overall moisture and seasonality. *Fernseea itatiaeae* (Wawra) Baker appeared to be considerably more sensitive to seasonality than to overall moisture.

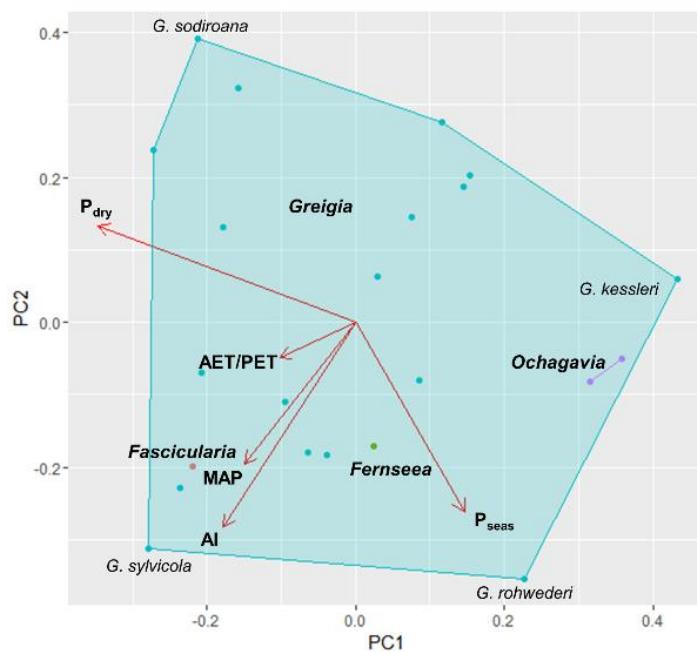

Figure A2.4.13. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for C₃ early-diverging Bromelioideae ($n = 22$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

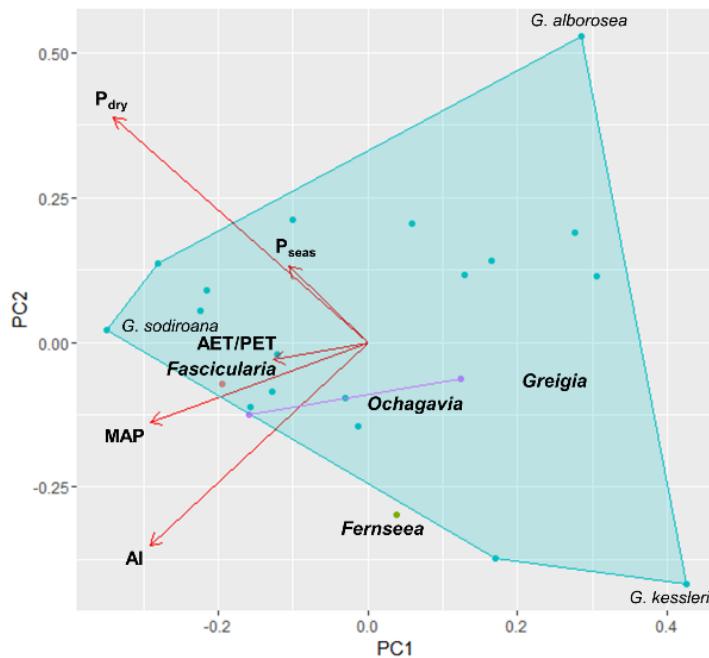

Figure A2.4.14. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for C₃ early-diverging Bromelioideae ($n = 22$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

CAM early-diverging Bromelioideae

There was a clear overall moisture vs. seasonality distinction when PCA was performed on hydrological habitat means for the CAM genera in the early-diverging Bromelioideae (Fig. A2.4.15). Among the CAM genera in the early-diverging Bromelioideae, the most distinctive genus was *Disteganthus*. All three species represented in the dataset clustered closely in the area of the PC1-PC2 climate space corresponding to high moisture and low seasonality. At the opposite end of the spectrum, the genera *Deinacanthon* and *Neoglaziovia* were associated with some of the driest and most seasonal environments. The genus with the broadest range of habitat means was *Bromelia*. Species such as *B. tubulosa* L.B.Sm. were associated with less seasonal, high-moisture habitats, and indeed this species co-occurs with *Disteganthus* spp. in northern Amazonia. Among *Bromelia* spp. associated with high seasonality, there was a distinction between species such as *B. irwinii* L.B.Sm. which inhabit regions with higher overall moisture, and species like *B. arenaria* Ule which are restricted to drier regions. In *Cryptanthus*, the only species with a high-moisture, aseasonal habitat was *C. pseudopetiolatus* Philcox. As its name suggests, this species again displays pseudopetiolate leaves. In more seasonal but relatively high-moisture environments occurred species such as *C. schwackeanus* Mez, which displays a C₃ δ¹³C signature (Crayn et al., 2015). Finally, the range of habitat means in the genus *Orthophytum* was centred furthest towards the drier, more seasonal corner of the PC1-PC2 climate space, but was still extensive. Species associated with the lowest overall moisture levels and moderate degrees of seasonality included the strongly xeromorphic, acaulescent rosette species *O. saxicola* (Ule) L.B.Sm., while caulescent species like *O. schulzianum* Leme & M.Machado were associated with more seasonal environments with higher overall moisture.

In terms of habitat range (Fig. A2.4.16), the greatest variation occurred among *Orthophytum* spp., followed by two other larger genera, *Cryptanthus* and *Bromelia*. Where some *Orthophytum* species (e.g. *O. saxicola*) showed relatively wide ranges in terms of overall moisture and seasonality, other species appeared to be constrained either by overall moisture or seasonality. The same was true for both *Cryptanthus* and *Bromelia*. *Ananas*, *Deinacanthon*, and *Disteganthus* species all showed moderately high wide ranges for both overall moisture and seasonality, with *Disteganthus* being the most strongly limited by seasonality among these smaller genera.

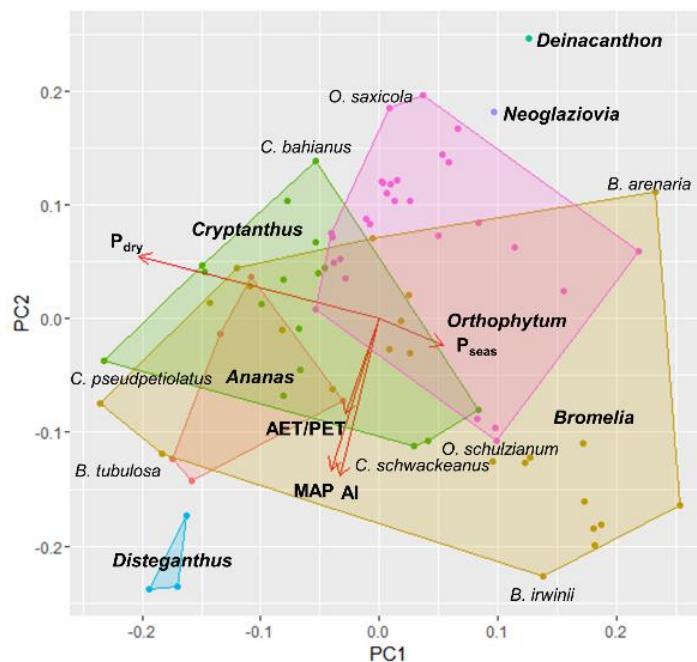

Figure A2.4.15. PC1-PC2 biplot based on PCA of mean values of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for CAM early-diverging Bromelioideae ($n = 77$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

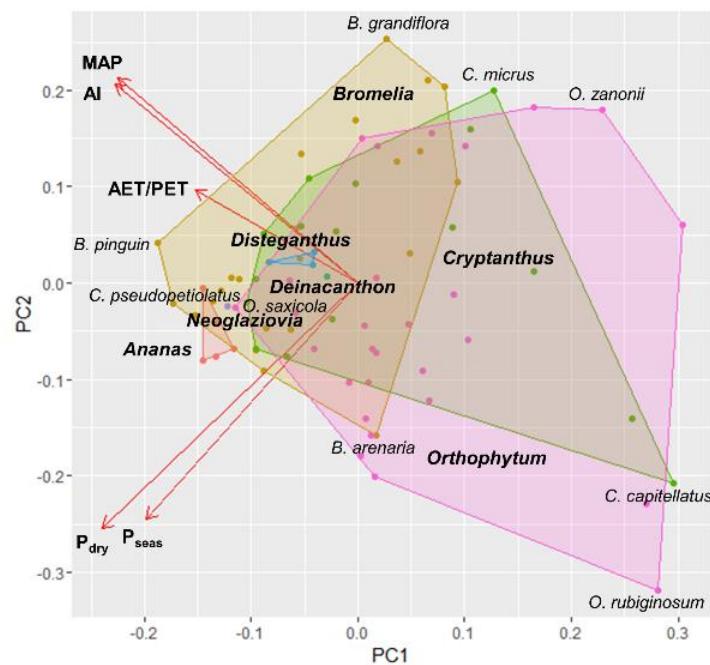

Figure A2.4.16. PC1-PC2 biplot based on PCA of ranges of bioclimatic variables (MAP, AI, AET/PET, P_{dry} , P_{seas}) for CAM early-diverging Bromelioideae ($n = 77$). Species scores are plotted and grouped by genus, with separate convex hulls covering all species belonging to each genus. PC1-PC2 scores for selected species are highlighted and arrows show bioclimatic variable loadings.

Table A3.1.1. Species used for drought resistance trait survey. Y/N in 'LES' column indicates whether species was included in the leaf economic trait survey. [‡]CAM $\delta^{13}\text{C}$ value in Crayn et al. (2015); [†]C₃-CAM; *C₃ $\delta^{13}\text{C}$ value in Crayn et al. (2015). Key to living collection sources: CUBG = Cambridge University Botanic Garden; MSBG = Marie Selby Botanical Gardens; RBGE = Royal Botanic Garden Edinburgh; RBGK = Royal Botanic Garden Kew.

Appendix 3.2

A3.2.1 Comparison of bench drying and overpressure methods for vulnerability curve construction

A comparison of bench drying and overpressure methods for vulnerability curve construction was made using four species of different functional types (*Pitcairnia integrifolia*, *Bromelia humilis*, *Vriesea fenestralis*, and *Aechmea aquilega*). Five replicate curves using each method were measured for each species. The results are shown plotted together in the following figure.

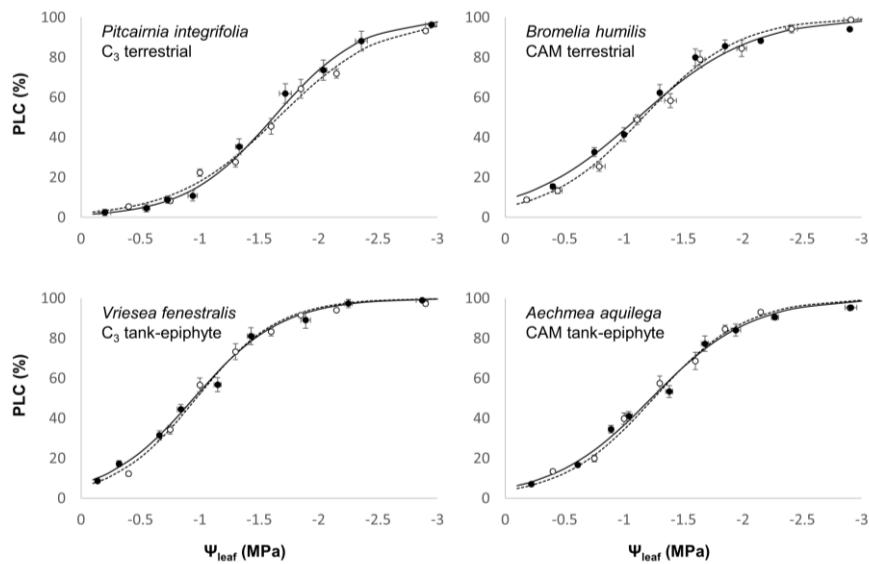

Figure A3.2.1. Comparison of leaf hydraulic vulnerability curves produced using overpressure and bench drying methods. Closed circles show mean data from the overpressure method, and open circles show mean data from bench drying method. Solid lines show sigmoidal response of percentage loss conductance (PLC) to leaf water potential (Ψ_{leaf}) fitted using overpressure method, and dashed lines show sigmoidal response of PLC to Ψ_{leaf} fitted using bench drying method. Error bars show \pm standard error of mean.

The shape of leaf hydraulic vulnerability curves and the location of the fitted inflection point at P_{50L} were very similar using either the overpressure or bench drying method for all four species tested (Fig. A3.2.1). While acknowledging the artefacts that the overpressure method could introduce into the data if it affects the structure of the mesophyll, on the basis of the high degree of consistency in vulnerability curves constructed using both approaches in these four species it was decided to use the overpressure method for the remaining species because of the much faster measurement cycle (ca. 8 hours compared with several days or more). The use of the overpressure method in other plant groups is not necessarily advocated, particularly those with less mechanically reinforced leaves, where it is likely to produce results considerably less consistent with more ‘natural’ dehydration.

Appendix 3.3

Table A3.3.1. Mean values (\pm SE) for leaf economic and hydraulic traits in 50 bromeliad species. Trait key: A_{\max} = maximum photosynthetic capacity; N_{leaf} = leaf nitrogen content; PNUE = photosynthetic nitrogen-use efficiency; LMA = leaf mass per unit area; g_{smax} = maximal stomatal conductance; iWUE = intrinsic water-use efficiency; P_{leaf} = leaf phosphorus content; C: N = ratio of leaf carbon to nitrogen content; R_L = respiration in the light; R_D = dark respiration; $\delta^{13}\text{C}$ = carbon isotope ratio; VED = vein-epidermis distance; IVD = interveinal distance; K_{leafmax} = maximal leaf hydraulic conductance; Ψ_{tlp} = leaf water potential at turgor loss point; ε = leaf bulk elastic modulus; C_{FT} = leaf capacitance at full turgor; P_{50S} = leaf water potential at 50% stomatal closure; P_{50L} = leaf water potential at 50% loss hydraulic conductance; SD = stomatal density; IAS = internal air space fraction.

A3.3.2 Mean values for drought resistance and bioclimatic traits for 376 bromeliad species

Table A3.3.2 Mean values of drought resistance and bioclimatic traits for 376 bromeliad species. Trait key: π_o = osmotic potential at full turgor; LMA = leaf mass per unit area; SWC = saturated water content; WMA = water mass per unit area; P_{seas} = precipitation seasonality; AI = aridity index. For π_o and SWC, SE < 0.03 for all species; for LMA and WMA, SE < 10 for all species.

Appendix 3.4

A3.4.1 Non-significant relationships among leaf economic and hydraulic traits specific functional types

Functional type	Variable 1	Variable 2	r^2	p
CAM atmospheric epiphyte	A_{\max}	$K_{leaf\max}$	-0.13	0.799
CAM terrestrial	A_{\max}	$g_{s\max}$	-0.11	0.561
CAM tank-epiphyte	A_{\max}	$g_{s\max}$	-0.14	0.959
CAM atmospheric epiphyte	A_{\max}	$g_{s\max}$	-0.11	0.678
CAM terrestrial	A_{\max}	IAS	-0.14	0.643
CAM atmospheric epiphyte	A_{\max}	IAS	0.15	0.161
CAM terrestrial	$g_{s\max}$	IAS	-0.13	0.608
CAM tank-epiphyte	$g_{s\max}$	IAS	0.08	0.235
CAM atmospheric epiphyte	$g_{s\max}$	IAS	-0.09	0.569

Table A3.4.1 Non-significant relationships between pairs of traits within specific functional types. Trait key:

A_{\max} = maximum photosynthetic capacity; $K_{leaf\max}$ = maximal leaf hydraulic conductance; $g_{s\max}$ = maximal stomatal conductance; IAS = internal air space fraction.

Appendix 3.5

A3.5.1 Numerical results of PCA for leaf economic and hydraulic traits

Component	Standard deviation	Proportion of variance	Cumulative proportion
PC1	3.11	0.48	0.48
PC2	1.93	0.19	0.67
PC3	1.43	0.10	0.77
PC4	1.12	0.06	0.83
PC5	0.91	0.04	0.88

Table A3.5.1. Results of principal components analysis (PCA) performed on all measured leaf economic and hydraulic traits for 50 bromeliad species.

Appendix 4.1

Table A4.1.1 (overleaf). Mean values of anatomical and bioclimatic characters quantified in vein placement survey for 376 bromeliad species. Trait key: IVD = interveinal distance; VED = vein-epidermis distance; L_{leaf} = leaf length; W_{leaf} = leaf width; APL = apoplastic hydraulic path length; t_{rehyd} = time for controlled rehydration; MAP = mean annual precipitation. Habitat key: DXS = desert and xeric shrubland; MFS = Mediterranean forest and scrub; TDF = tropical dry forest; TMF = tropical moist forest; TRA = Andean alpine tundra. For additional bioclimatic data and details of provenance of living material, see appendices to Chapter 3.

A4.1.2 Results of survey of venation architecture, vascular anatomy, and components of hydraulic conductance

Functional type	Species	Venation pattern	Leaf xylem vessels	$ P_{50x} $ (MPa)	$\pm SE$	1° vein 1° conduit d (μm)	$\pm SE$	1° vein 2° conduit d (μm)	$\pm SE$	2° vein 1° conduit d (μm)	$\pm SE$

Table A4.1.2. Mean values of venation structural-functional traits for 50 bromeliad species. Trait key: P_{50x} = leaf water potential at 50% loss xylem hydraulic conductance; $1^{\circ}/2^{\circ}$ vein $1^{\circ}/2^{\circ}$ conduit d = diameter of primary/secondary conduits in primary/secondary veins; IVD_i = order-specific interveinal distance; t/b^2 = thickness-to-span ratio of primary xylem conduits in primary veins; $1^{\circ}/2^{\circ}/3^{\circ} \Sigma K^*$ = vein-specific hydraulic conductance estimated from anatomical characters; $p 1^{\circ}$ = proportion of total anatomically-estimated xylem hydraulic conductance contributed by 1° veins; K_x = measured xylem hydraulic conductance; K_{ox} = calculated extra-xylary hydraulic conductance; K_{leaf} = measured whole-leaf hydraulic conductance.

A4.1.3 Extra-xylary anatomical characterisation

Table A4.1.3. Mean values of proportion of leaf cross-section occupied by different extra-xylary compartments for 50 bromeliad species. LA = leaf anatomical design, as described in text; BSE = bundle sheath extension.

Appendix 4.2

A4.2.1 Heuristic model of vein placement physiology- Methods

An heuristic model of physiological fitness was designed, based on multiplicative fitness components (w_i). For the purposes of this model, ‘fitness’ is defined simply as a relative measure of physiological adaptation to a particular environmental context. The first step in model construction was to define the relationships (‘linker functions’) between IVD and VED and a set of internal variables. All internal variables and linker functions are displayed in Table A4.2.1. The internal variables included LMA, leaf hydraulic capacitance at full turgor (C_{FT}) and leaf area, as well as relative indices of leaf hydraulic vulnerability (V_H) and leaf construction cost (CC). The method of DeBoer et al. (2016) was used to compare the ability of an observed leaf anatomical arrangement (i.e. a specific combination of LT, IVD and VED values) to provide hydraulic support for gas exchange with the ability of the ‘optimal’ arrangement ($IVD = VED$) to achieve the same. This approach assumes a key role for vein placement in driving variation in hydraulic conductance, a hypothesis which received moderate support in the context of the bromeliads in the analyses presented in **Chapter 3** and for which empirical equations could be parameterised. Another comparative index was constructed, defined by the balance between the potential rate of hydraulic recharge with the observed anatomical arrangement and the equivalent potential of a similar leaf with the ‘optimal’ arrangement. The rate of recharge was assumed to be linearly related to the quotient of leaf hydraulic capacitance and conductance.

Internal variable	Linker function	Normalisation	Explanation
Leaf mass per unit area, LMA (g m^{-2})	$LMA = 10^{(0.5294 \times \log VED + 1.2978)}$	$LMA_{rel} = \frac{LMA}{LMA_{max}}$ where LMA_{max} is the upper bound for LMA observed in the species set (800 g m^{-2})	Empirical relationship derived from anatomical measurements
Leaf hydraulic capacitance at full turgor, C_{FT} ($\text{mmol MPa}^{-1} \text{m}^{-2}$)	$C_{FT} = 1000 \times 10^{(0.6932 \times \log VED - 0.8932)}$	$C_{FT,rel} = \frac{C_{FT}}{C_{FT,max}}$ where $C_{FT,max}$ is the upper bound for C_{FT} observed in the species set ($33,000 \text{ mmol MPa}^{-1} \text{m}^{-2}$)	Empirical relationship derived from anatomical measurements
Hydraulic vulnerability, V_H (relative)	$V_H = \frac{1}{1 + e^{(-2 \times (IVD/VED - 1))}}$	n/a	Heuristic relationship based on logic proposed by Zwieniecki and Boyce (2014)
Adaptation for hydraulic recharge, dt_{hyd} (%)	$dt_{hyd} = 100 \times \frac{t_{hyd_opt} - t_{hyd}}{t_{hyd}}$	$dt_{hyd,rel} = \frac{dt_{hyd}}{dt_{hyd,max}}$ where $dt_{hyd,max}$ is the upper bound for dt_{hyd}	Hydraulic recharge rate assumed to be controlled by leaf

	$t_{hyd} = \frac{C_{FT}}{K_{leaf}}$	observed in the species set (50%)	hydraulic conductance
	$t_{hyd_opt} = \frac{C_{FT}}{K_{leaf_opt}}$		
Leaf area (mm^2)	$Area = l_{leaf} \times w_{leaf}$ $l_{leaf} = 10^{(-0.232 \times (IVD/VED) + 2.86)}$ $w_{leaf} = 10^{(0.253 \times \log(l_{leaf}) + 1.139)}$	$Area_{rel} = \frac{Area}{Area_{max}}$ where $Area_{max}$ is the upper bound for leaf area observed in the species set ($47,500 \text{ mm}^{-2}$)	Empirical relationships derived from anatomical measurements
1- leaf construction cost, CC (relative)	$CC = 1 - \left(\frac{1}{1 + e^{-(IVD/VED-1)}} \right)$	n/a	Heuristic relationship assuming construction cost inversely related to IVD/VED. N.B. Higher values indicate lower leaf construction cost.
Adaptation for productivity, δA (%)	$\delta A = 100 \times \frac{A_{int} - A_{int_opt}}{A_{int}}$ $A_{int} = \left(1 - \frac{\Gamma^*}{C_{i,int}} \right) \times \left(\frac{v_{cmax} \times C_{i,int}}{C_{i,int} + k_c \left(1 + \frac{O}{k_o} \right)} \right) - R_d$ $C_{i,int} = C_a \times \frac{\Delta_{leaf} - a}{b}$	$\delta A_{rel} = \frac{\delta A}{\delta A_{max}}$ where δA_{max} is the upper bound for δA observed in the species set (20%)	Semi-empirical system of equations based on De Boer et al. (2017). Compares theoretical integrated carbon gain achievable with actual anatomical arrangement with carbon gain achievable with 'optimal' arrangement (IVD = VED). Re-parameterised using anatomical and physiological measurements.
	where for C ₃ species $a = 4.4$ and $b = 22.6$ (Farquhar et al., 1982); for CAM species $a = -8.6$, $b = 23.9$.		
	$\Delta_{leaf} = 1000 \times \frac{\delta_{air} - \delta_{leaf}}{1 + \delta_{leaf}}$ (Farquhar et al., 1989)		
	$A_{int_opt} = g_{sc_opt} \times (C_a - C_{i_opt})$		
	$g_{sc_opt} = \frac{g_{sw_opt}}{1.6}$		Assumes photosynthesis is principally limited by carboxylation.
	$g_{sw_opt} = \frac{E_{opt}}{VPD}$		
	$E_{opt} = K_{leaf_opt} \times \Delta\Psi_{leaf}$		
	$K_{leaf_opt} = \frac{6707}{((LT^2/4) + 0.078 \times (IVD_{0.5}/VED_{0.5})^2 \times LT^2)^{1.4}}$		
	$IVD_{0.5} = VED_{0.5} = \frac{IVD + VED}{2}$		
	$\Delta\Psi_{leaf} = \frac{E_{int}}{K_{leaf}}$		

$$E_{int} = 1.6 \times g_{sc,int} \times VPD$$

$$g_{sc,int} = \frac{A_{int}}{C_a - C_{i,int}}$$

$$K_{leaf} = \frac{6707}{((LT^2/4) + 0.078 \times (IVD/VED)^2 \times LT^2)^{1.4}}$$

Table A4.2.1. Model internal variables and linker functions connecting internal variables to IVD and VED.

Table A4.2.2 shows the methods and values used for photosynthetic parameters in modelling fitness component w_9 (see below). Several key parameters were derived from coupled gas exchange and chlorophyll fluorescence measurements performed according to the protocol of Bellasio et al. (2016). These measurements were performed for a small set of representative C₃ and CAM species (the latter during Phase IV RuBisCO-mediated CO₂ fixation), and mean values of fitted parameters were then used for all C₃ and CAM species respectively. Further details are provided in **Appendix 4.1**. This approach assumes that variation in photosynthetic parameters among species of the same photosynthetic pathway is relatively insignificant. This assumption is recognised as a potential limitation, although variation in fitted parameters among those species which were characterised by gas exchange and chlorophyll fluorescence measurements was relatively low.

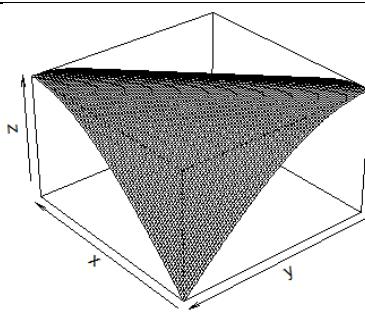

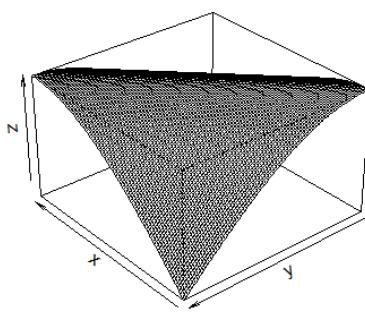

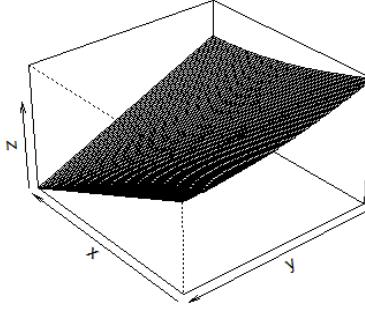

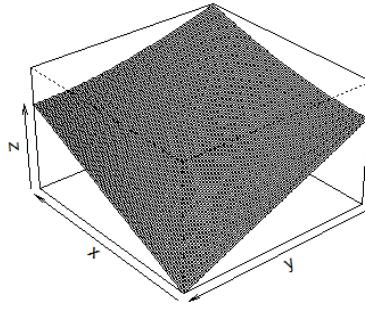

Parameter	Definition	Value	Method of estimation
F*	Respiration-adjusted CO ₂ compensation point (ppm)	48 (C ₃) 10 (CAM)	Gas exchange measurements (Bellasio et al., 2016)- see Appendix 4.1
V _{cmax}	Maximum carboxylation rate (μmol m ⁻² s ⁻¹)	55 (C ₃) 65 (CAM)	Gas exchange and chlorophyll fluorescence measurements (Bellasio et al., 2016)- see Appendix 4.1
k _c (1+(O/k _o))	Apparent k _m (CO ₂) of RuBisCO (μM)	550 (C ₃) 320 (CAM)	Gas exchange and chlorophyll fluorescence measurements (Bellasio et al., 2016)- see Appendix 4.1
R _D	Dark respiration rate (μmol m ⁻² s ⁻¹)	0.69 (C ₃ mesic terrestrial) 0.64 (C ₃ succulent terrestrial) 0.35 (CAM terrestrial)	Mean values calculated by functional type from data reported in Chapter 3
δ _{air}	δ ¹³ C air (‰)	-8.10	Arbitrary selection from within range of values reported in Affek et al. (2007)
δ _{leaf}	δ ¹³ C leaf (‰)	Species-specific	Retrieved from Crayn et al. (2015)
C _a	Atmospheric CO ₂ concentration (ppm)	400	Based on recent trends reported in Scripps CO ₂ measurements (Scripps CO ₂ Program 2016)
VPD	Leaf-air vapour pressure deficit (kPa)	Species-specific	Representative reliable presence-point near centre of species' geographical range selected manually from GBIF data and used to retrieve mean

2011-2015 absolute atmospheric vapour pressure (AVP, kPa) from a rasterised version of the CRU TS v3.24.01 dataset (Climate Research Unit, University of East Anglia). Water vapour in internal leaf air spaces was assumed to be saturating, leaf temperature was standardised to 28 °C for calculation of saturated vapour pressure (SVP, kPa), and VPD was calculated as AVP-SVP

Table 4.2.2. Parameters used for modelling of fitness component w_9 .

The second step in model construction was to define the relationships between internal variables, environmental variables, and the values of a series of relative fitness components. These semi-quantitative, heuristic relationships are outlined and justified in Table A4.2.3. Two environmental variables were selected as representative of the major axes of variation in bromeliad hydrological habitat space (see **Chapter 2**): the aridity index (AI, mm mm⁻¹) and precipitation seasonality (P_{seas} , %). Relative fitness components w_8 and w_9 were simply set as equal to CC and δA_{rel} respectively, as it was assumed that higher values of these traits would be advantageous under all environments.

Fitness component	Internal variable	Environmental variable	Relationship and description	Rationale
w_1	LMA_{rel}	AI_{rel}	$z = \cos(1.5x - 1.5y)$	Less tough, shorter-lived leaves favoured under more mesic conditions, and tougher, longer-lived leaves favoured under more arid conditions (Chapter 3)
w_2	$C_{FT,\text{rel}}$	AI_{rel}	$z = \cos(1.5x - 1.5y)$ <p style="text-align: center;">Fitness maximised when LMA_{rel} and AI_{rel} equal</p>	Advantage of water storage rises under increasingly arid conditions (Chapter 3)

				Fitness maximised when $C_{FT,rel}$ and Al_{rel} equal	
w_3	$C_{FT,rel}$	$P_{seas,rel}$	$z = \cos(1.5x - 1.5y)$		Advantage of water storage rises as water availability is concentrated in increasingly seasonal precipitation events (Ellenberg, 1981)
w_4	V_H	Al_{rel}	$z = \sqrt{(x - 1)^2 + (y - 1)^2}$		Hydraulic vulnerability less strongly selected against in more humid environments (Zwieniecki and Boyce, 2014), while high hydraulic vulnerability in arid environments could lead to catastrophic physiological dysfunction
w_5	$\delta t_{hyd,rel}$	Al_{rel}	$z = \sqrt{x^2 + (y - 1)^2}$		Efficient hydraulic recharge assumed to be crucial in arid environments (Griffiths, 2013), but could also be beneficial for species occupying more mesic sites
w_6	$\delta t_{hyd,rel}$	$P_{seas,rel}$	$z = \sqrt{x^2 + (y - 1)^2}$		Efficient hydraulic recharge assumed to be crucial under episodic

				precipitation regimes (Ellenberg, 1981), but could also be beneficial for species occupying less seasonal sites
			Fitness maximised when $P_{seas,rel}$ low and $\delta t_{hyd,rel}$ high, and minimised when $P_{seas,rel}$ high and $\delta t_{hyd,rel}$ low	
w ₇	Area _{rel}	AI _{rel}	$z = \sin(1.5x + 1.5y)$ 	High leaf area assumed to be advantageous in more mesic environments due to competitive interactions, and less advantageous in more arid environments due to increased for water loss
w ₈	CC	n/a	Fitness maximised when Area _{rel} = -AI + 1	
w ₉	δA_{rel}	n/a	n/a	Low leaf construction costs <i>per se</i> assumed to be advantageous in any environment
				Maximisation of potential carbon gain assumed to be advantageous in any environment

Table A4.2.3. Relationships between normalised internal variables and fitness components (w_i).

For a set of 31 representative terrestrial species native to contrasting areas of hydrological habitat space and of different functional types, the model was parameterised with anatomical traits (leaf thickness, LT; IVD; VED), mean AI and P_{seas} scores retrieved from **Chapter 2**, and carbon isotope values from the Crayn et al. (2015) dataset. Anatomical traits were measured by light microscopy using leaf material sourced and sampled as described in **Chapter 3**. At least ten replicate leaves were sampled per species. Species-specific traits are summarised in Table A4.2.4.

Table A4.2.4. Anatomical parameters, carbon isotope ratios from Crayn et al. (2015), and bioclimatic scores for all species used in IVD: VED modelling.

The model was fitted for each species and the output (fitness components) retrieved, including the product of all fitness components (w_{tot}). The model was then solved for the optimal combination of IVD and VED for maximum w_{tot} (w_{fit}), holding all other parameters constant. The model was constrained to find solutions for which $50 \mu\text{m} \leq \text{IVD} \leq 1000 \mu\text{m}$, $50 \mu\text{m} \leq \text{VED} \leq 3000 \mu\text{m}$ and $\text{VED} \leq (\text{LT}/2)$. These constraints were based on the lower and upper bounds on IVD and VED observed during anatomical characterisation, and the tendency for the vascular plane never to fall closer to the adaxial than to the abaxial epidermis. The results of model optimisation were compared with the results obtained with the observed anatomical parameters by calculating $w_{fit}-w_{tot}$ and $100 \times (w_{tot}/w_{fit})$, and the ratios between the observed and fitted values of IVD, VED, and IVD: VED.

In addition to the analyses described above, the optimal combination of IVD and VED for maximum w_{tot} was modelled across $\text{AI-P}_{\text{seas}}$ climate space for three hypothetical trait combinations designed to represent the three focal functional types (C_3 mesic terrestrial, C_3 succulent terrestrial, and CAM terrestrial). The relevant traits are outlined in Table A4.2.5.

Functional type	$\delta_{\text{leaf}} (\text{\textperthousand})$	VPD (kPa)	LT (μm)
C_3 mesic terrestrial	-28.00	1.20	200
C_3 succulent terrestrial	-23.00	1.80	900
CAM terrestrial	-12.00	2.40	2000

Table A4.2.5. Hypothetical trait combinations used to represent idealised examples of bromeliads of different terrestrial functional types for solving for optimal IVD and VED.

The same model constraints were used as in species-specific optimisation outlined above. For each functional type, model runs were performed using different combinations of AI and P_{seas} . AI was varied between 2,000 and 23,000 mm mm^{-1} at 3,000 mm mm^{-1} intervals, while P_{seas} was varied between 20 and 120% at 25% intervals. The resulting IVD: VED values were then transferred to R , and the ‘loess’ function was used to perform localised second-degree polynomial regression fitting, with the smoothing parameter (α) set to 0.25. Surface plots of the optimal IVD: VED ratio as a function of AI and P_{seas} were produced using the ‘wireframe’ function of the ‘lattice’ package (Sarkar, 2008).

A4.2.2 Heuristic structure-function modelling- Results

Fitness component scores (w_i) for all species are displayed by functional type in Table A4.2.6. Mean values differed significantly between functional types only for w_7 ($F = 3.58, p = 0.041$) and w_9 ($F = 4.56, p = 0.019$). In the case of w_7 , which links leaf area with AI, the highest scores occurred in C₃ succulent terrestrials and the lowest in CAM terrestrials. For w_9 , which reflects the ability of hydraulic supply to meet demand, the highest scores occurred in CAM terrestrials and the lowest in C₃ mesic terrestrials. Although differences between functional types in mean scores for other fitness components were not statistically significant, scores for w_3, w_4, w_5 and w_6 tended to be higher in CAM terrestrials and lower in C₃ succulent terrestrials, while scores for w_1 and w_2 tended to be higher in C₃ mesic terrestrials and lower in C₃ succulent terrestrials and w_8 was generally higher in C₃ mesic terrestrials and lower in CAM terrestrials. When all fitness components were multiplied to provide species-specific scores of w_{tot} , these values did not differ significantly between functional types, but tended to be higher in C₃ mesic terrestrials and lower in C₃ succulent terrestrials.

Table A4.2.6. Observed IVD: VED ratios and modelled fitness components (w_i) for 31 bromeliad species of contrasting functional type.

The relationships between observed IVD: VED and calculated individual fitness components (w_i) and w_{tot} are displayed in Fig. A4.2.1. These relationships are reflective of the model structure, and highlight how the model generated a spectrum of values for each fitness component.

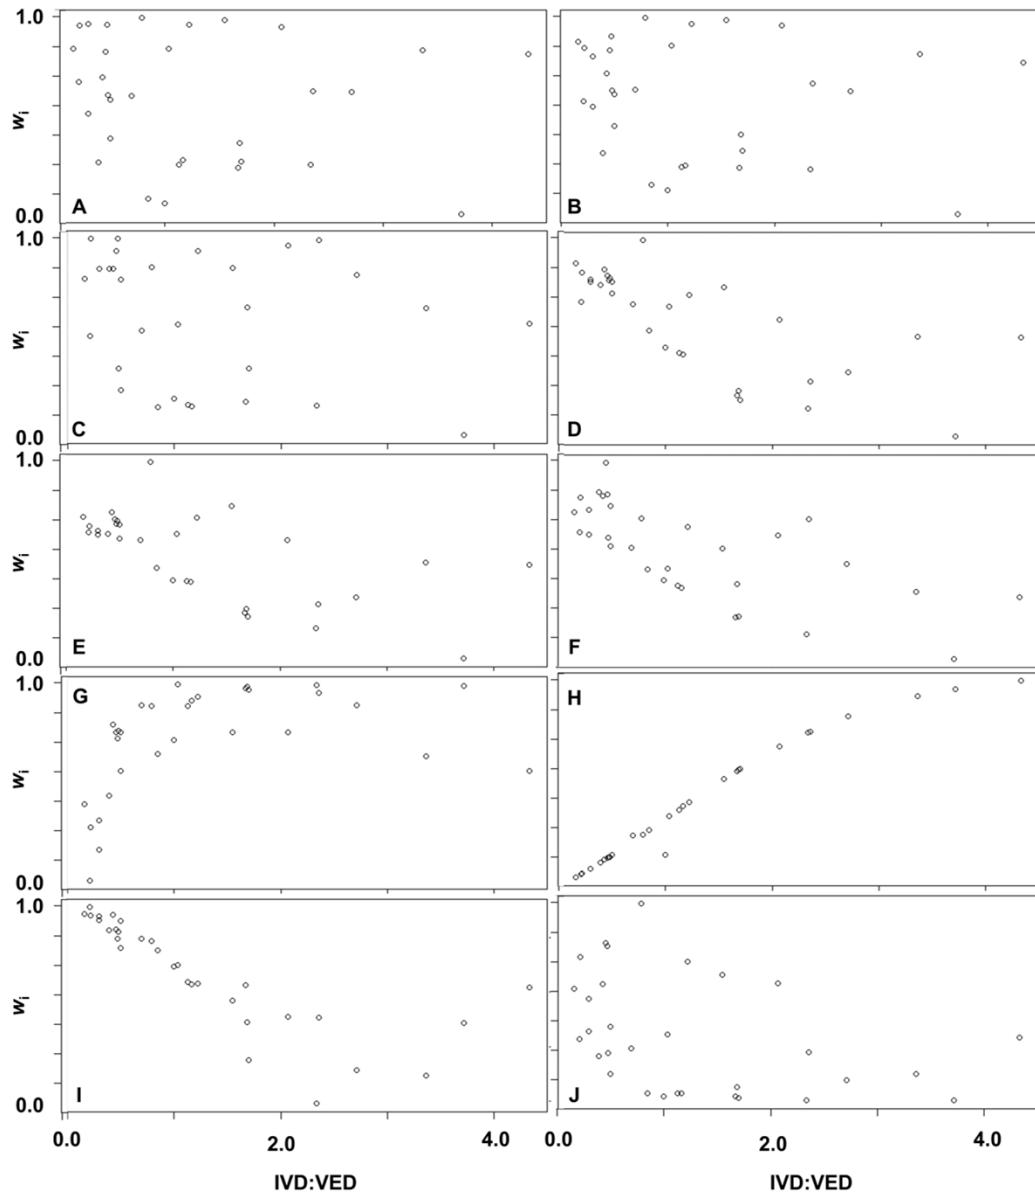

Figure A4.2.1. Relationships between fitness components (w_i) and observed IVD: VED for 31 bromeliad species.
a) w_1 ; b) w_2 ; c) w_3 ; d) w_4 ; e) w_5 ; f) w_6 ; g) w_7 ; h) w_8 ; i) w_9 ; j) w_{tot} .

The optimal values of IVD and VED were next calculated for each species by maximising w_{tot} subject to the constraints described in A4.2.1.3. The maximised value of w_{tot} was termed w_{fit} . The results are displayed in Table A4.2.7.

The squared residuals between actual values of IVD, VED, and IVD: VED and the fitted optimal values displayed broad variation. Although there were no significant differences between functional types in terms of the values of squared residuals (IVD: $F = 0.72, p = 0.497$; VED: $F = 0.47, p = 0.631$), lower values tended to occur in succulent CAM terrestrials, while the median value and range were substantially higher for C₃ mesic terrestrials in particular. The relationship between observed IVD: VED and IVD_{fit}: VED_{fit} is displayed in Fig. A4.2.2a. There was a relatively strong positive correlation between the observed and modelled ratios ($r^2 = 0.48, p < 0.001$), with the modelled optimal ratio tending to be approximately 25% of the observed ratio. Fig. A4.2.2b shows the strong positive correlation between w_{tot} and w_{fit} ($r^2 = 0.53, p < 0.001$). Functional type was a significant factor for the absolute difference between w_{fit} and w_{tot} ($F = 4.99, p = 0.014$), with slightly lower values in most CAM terrestrials than in C₃ succulent terrestrials, and substantially higher values occurring among many C₃ mesic terrestrials. Although the difference in $100 \times (w_{tot}/w_{fit})$ for functional types was not statistically significant ($F = 2.10, p = 0.141$), values tended to be somewhat lower among CAM terrestrials than in the other two functional types. Overall, these results are consistent with the conclusion that the observed vein placement of CAM terrestrials is closest to the theoretical optimum predicted by the simple heuristic model presented here. The stronger departure of observed vein placement from predicted optima in species of other functional types is consistent with alternative physiological or developmental factors being more important determinants of vein placement in these groups.

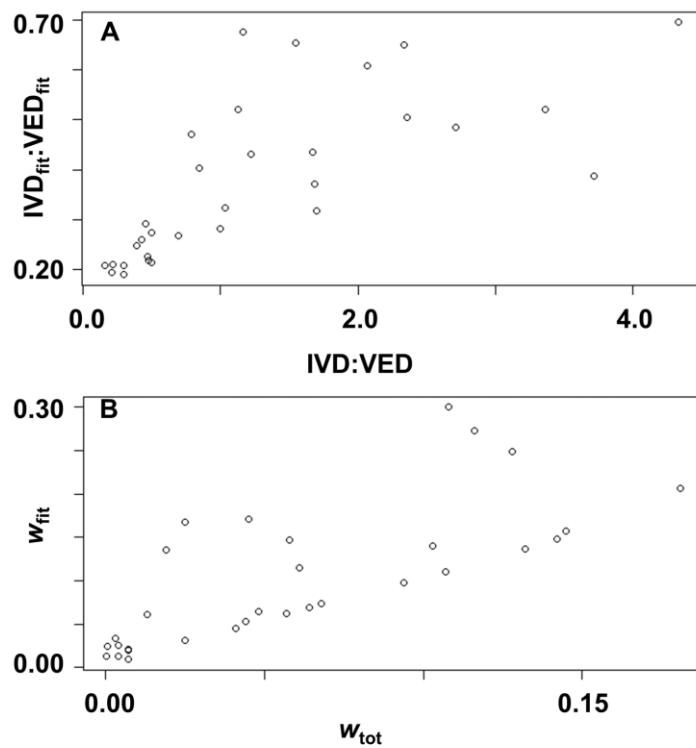

Figure A4.2.2. a) Relationship between observed IVD: VED and modelled optimal IVD_{fit} : VED_{fit} . b) Relationship between w_{tot} calculated from observed vein placement and w_{fit} based on modelled optimal vein placement.

The relationships between IVD: VED and w_{fit} , w_{fit} - w_{tot} , and the ratio of w_{tot} to w_{fit} are displayed in Fig. A4.2.3. While there was no correlation between the observed value of IVD: VED and w_{fit} (Fig. A4.2.3a), there was a positive correlation between IVD: VED and w_{fit} - w_{tot} ($r^2 = 0.30$, $p < 0.001$; Fig. A4.2.3b). There was an even stronger positive correlation between IVD: VED and the ratio of w_{fit} to w_{tot} ($r^2 = 0.61$, $p < 0.001$; Fig. A4.2.3c). These results are again consistent with any adaptive advantage of apparent ‘overinvestment’ in veins ($IVD: VED \gg 1$) being based on other (perhaps non-hydraulic) aspects of species’ ecophysiology not represented in the model structure.

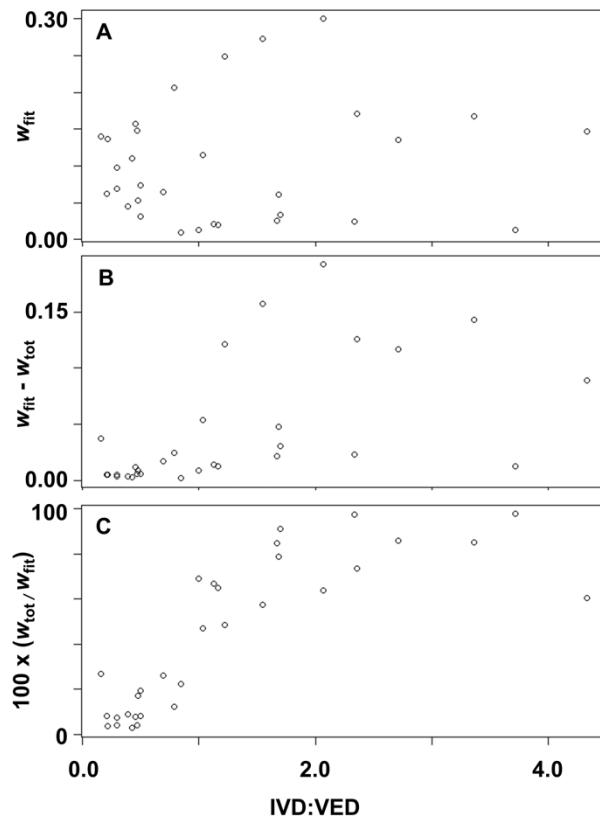

Figure A4.2.3. Relationships between IVD: VED and measures of optimisation modelling output for 31 bromeliad species: a) w_{fit} ; b) $w_{fit}-w_{tot}$; c) $100 \times (w_{tot}/w_{fit})$.

There was a strong positive correlation between w_{fit} and species mean AI score ($r^2 = 0.64, p < 0.001$; Fig. A4.2.4a), and a negative correlation between w_{fit} and species mean P_{seas} score ($r^2 = 0.45, p < 0.001$; Fig. A4.2.4b). Thus the model was able to find higher w_{fit} for species from more mesic, aseasonal habitats, which is consistent with the possibility that it is perhaps easier to balance competing physiological demands in such environments.

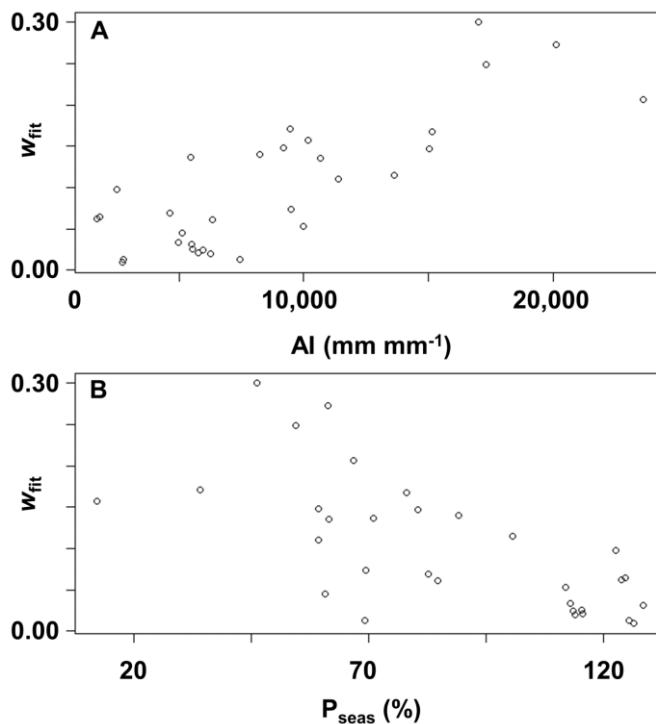

Figure A4.2.4. Relationships between bioclimatic factors and modelled optimised fitness (w_{fit}) for 31 bromeliad species. a) w_{fit} vs. Al; b) w_{fit} vs. P_{seas} .

In addition to the species-specific optimisation runs described above, optimal IVD: VED was also solved for across the Al- P_{seas} climate space for idealised representatives of three focal functional types (C_3 mesic terrestrials, C_3 succulent terrestrials and CAM terrestrials). The results are displayed as surfaces in Fig. A4.2.5. Consistent with the poor model performance for individual C_3 mesic terrestrial species, the surface of optimal IVD: VED values for the idealised C_3 mesic terrestrial was equal to 0.5 across the entire climate space (Fig. A4.2.5a), which was driven by constrained maximisation of VED and minimisation of IVD. By contrast, for both the idealised C_3 succulent terrestrial (Fig. A4.2.5b) and CAM terrestrial (Fig. A4.2.5c), the surface showed complex, similar topology. At higher values of Al, the optimal value of IVD: VED increased steeply, reaching a global maximum where high Al was combined with low P_{seas} (i.e. the most mesic and aseasonal environments). Conversely, the lowest optimal values of IVD: VED occurred at low Al and high P_{seas} (i.e. the most xeric and seasonal environments). This pattern was consistent with the observed relationships between vein placement and habitat association across bromeliad species.

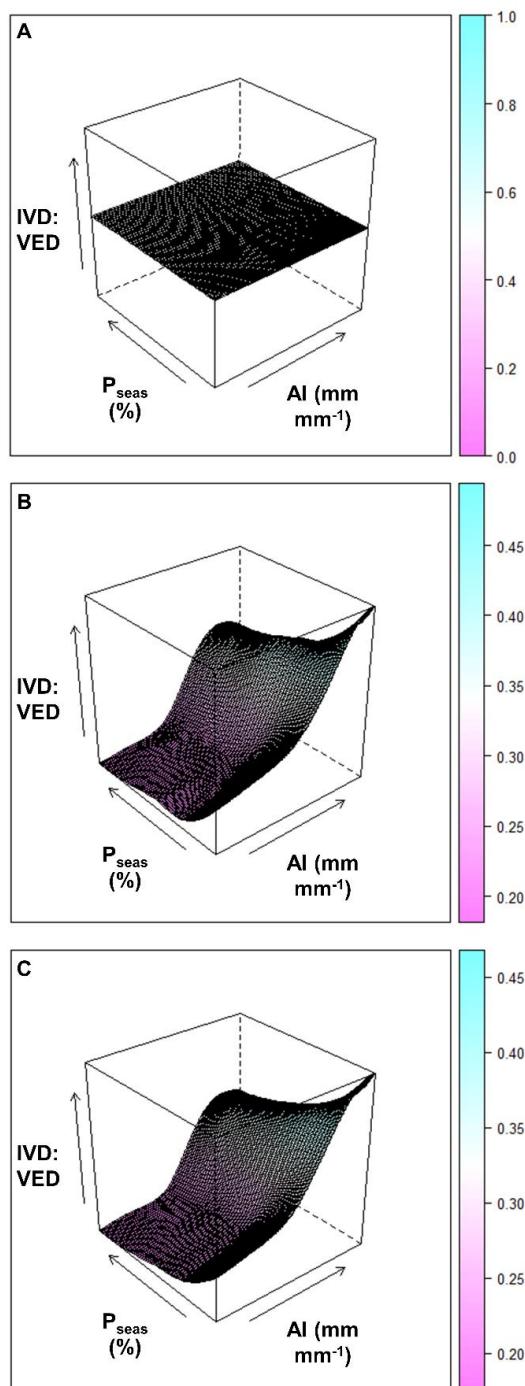

Figure A4.2.5. Optimal solutions for IVD: VED across P_{seas} -AI climate space for idealised representatives of three bromeliad functional types: a) C₃ mesic terrestrial; b) C₃ succulent terrestrial; c) CAM terrestrial.

A.4.2.3 Heuristic structure-function modelling- Discussion

Alongside the extensive empirical survey of vein placement and analysis of correlations with functional type and habitat occupancy, further insights into the functional significance of variation in vein placement were gained through the implementation of a simple model linking relevant anatomical parameters with heuristic fitness components. The structure of the model was based on

a combination of empirically-defined trait correlations and theoretical mechanistic relationships between relative trait values and probability of plant success in different areas of hydrological habitat space defined by the aridity index (AI) and precipitation seasonality (P_{seas}). The model was not intended to be fully quantitative, and ignored some physiological mechanisms that could link vein placement with plant fitness. However, it succeeded in generating several interesting insights regarding the possible relative importance of vein placement for ecophysiological adaptation and differentiation among terrestrial bromeliads of different functional types. Because the model was to a large extent based on hydraulic physiological factors, the fact that the observed values of IVD: VED were closer to the fitted optimal values of IVD: VED in succulent species than in non-succulent species suggests that hydraulic optimisation of vein placement could be more important in the ecophysiology of succulent terrestrial bromeliads. This is consistent with the hypothesis that the efficiency of vein-mediated water distribution is a key component of the process of recharge in succulents. The model also demonstrated how low IVD could support the relatively high rates of gas exchange observed in some C₃ succulent terrestrials (e.g. *Puya* spp., see **Chapter 3**). Because of the use of photosynthetic parameters fitted to data relating to Phase IV CO₂ fixation, the model probably underestimated the benefit of disproportionately high VED in succulent CAM species. From observations made during anatomical characterisation it was clear that in these plants high VED was associated with an increased number of chlorenchyma cell layers, and with larger cells. This provides a large capacity for PEPC-mediated CO₂ fixation during Phase I and storage of organic acids in chlorenchyma cell vacuoles. Organic acid storage capacity is a key limiting factor for nocturnal carbon assimilation in CAM plants (Steudle et al., 1980; Silvera et al., 2010). Selection for high VED as a correlate of photosynthetic capacity in CAM bromeliads could therefore complement selection for low IVD as a correlate of hydraulic recharge capacity in driving low IVD: VED ratios in these species.

By contrast, the greater disparity between observed and modelled optimal IVD: VED ratios in non-succulent C₃ mesic terrestrials suggests that other physiological factors could be more important determinants of the fitness of contrasting vein placement phenotypes. For instance, wider leaves may be selected for in shade-adapted species, but the achievement of high leaf width may be developmentally contingent on high IVD (as suggested by the data for C₃ tank-epiphytes presented above). In such environments, the hydraulic disadvantages of effective underinvestment in veins may be of limited consequence for plant water-use.

Functional type	Species	IVD (μm)	VED (μm)	IVD: VED	IVD _{fit} (μm)	VED _{fit} (μm)	IVD _{fit} : VED _{fit}	(IVD - IVD _{fit}) ²	(VED - VED _{fit}) ²	(IVD: VED - IVD _{fit} : VED _{fit}) ²	w _{tot}	w _{fit}	w _{fit} -w _{tot}	100* w _{fit} -w _{tot} /w _{fit}

Table A5.1.1. Responses of steady-state gas exchange parameters (stomatal conductance to water vapour, g_{sw} ; transpiration rate, E ; assimilation rate, A ; water-use efficiency, WUE) to increasing levels of leaf-air vapour pressure deficit (VPD), based on five replicate curves for each of 93 bromeliad species.

Appendix 6.1

A6.1.1 Description of forest physiognomy and floristics on Trinidad and Tobago

At the very highest elevations on El Cerro del Aripo and El Tucuche, elfin woodland (EW) occurs. This vegetation is characterised by abundant mosses and lichens, short-statured trees (mostly *Clusia intertexta* Britton), and a temperate climate with high evaporative potential but no seasonal drought.

Montane Forest (MF) *sensu* Beard (1946) of the *Richeria grandis* Vahl - *Eschweilera tenax* (Moritz ex O.Berg) Miers association occurs immediately below EW. This formation is best developed on the Aripo massif (around the peaks of El Cerro del Aripo, Morne Bleu and Chaguraramal) and on El Tucuche. MF displays luxuriant herbaceous ground vegetation and epiphytic growth, with tree-ferns and palms making a major contribution to the structure of the understorey. There is occasional evidence of wind damage, particularly on north-facing slopes. According to Beard the temperature range in MF is 15.0 -18.3°C, while Pittendrigh (1948) suggests annual rainfall in MF could be in excess of 6350 mm, and is sufficiently evenly distributed as to prevent the occurrence of seasonal drought.

Lower Montane Forest (LMF) extends across much of the remainder of the Main Ridge and down the north-south ridges between the Santa Cruz Valley and Cumaca. LMF is also found along the St David's Ridge and across much of the lower hills between the St David's Ridge and the Northeast Coastal Hills south and east of Grande Riviere. The typical association of this forest formation is *Byrsinima spicata* (Cav.) Rich. ex Kunth - *Licania ternatensis* Hook.f. ex Duss - *Sterculia pruriens* (Aubl.) K.Schum. More isolated pockets of LMF occur on headlands along the north coast such as on either side of Maracas Bay, and also on St Ann's Peak above Port-of-Spain and on Morne Catherine above Chaguraramas. The woody flora of the LMF is rich, while the ground vegetation is poorly developed and the epiphytic flora impoverished. Pittendrigh estimates an average annual rainfall of ca. 5000 mm in LMF, and Beard describes the climate of LMF as 'sub-tropical' and lacking seasonal drought, with a temperature range of 16.7 - 20°C.

North of the Main Ridge and to the immediate east of Cumaca, LMF transitions to an Evergreen Seasonal Forest (ESF) association, *Aniba panurensis* (Meisn.) Mez/A. *citrifolia* (Meisn.) Mez - *Carapa guianensis* Aubl./*Licania heteromorpha* Benth. This ESF presents a continuous canopy of mesophyllous trees that often show buttressing, and an understorey with many palms. Beard (1946a) suggested that ESF experiences three months of drought per year. In two large areas north of Cumaca and Platanal there is a Seasonal Montane Forest (SMF) formation, comprising the *Inga macrophylla* Willd. - *Guarea guidonia* (L.) Sleumer association. This formation is edaphically

determined, occurring on limestone covered with extremely thin soils. Regular mists provide moisture for luxuriant epiphytic growth and herbaceous ground vegetation in SMF.

At lower elevations in the valleys to the south of the Main Ridge there is a mixed secondary forest including abandoned fruit trees formerly in cultivation. The lowland forests around the Northern Range also include a highly unusual ESF association, *Mora excelsa* Benth. - *Carapa guianensis*/*Pentaclethra macroloba* (Willd.) Kuntze. In these 'mora forests', *M. excelsa* (Fabaceae) dominates to the extent that the upper canopy is virtually monospecific (Beard, 1946). Mora forest occurs throughout the Matura basin and there is also a smaller area north of the St David's Ridge near Paria Bay. Along the fringe of the North Coast and across much of the north-east headland around Toco there is a Deciduous Seasonal Forest (DSF) formation, with *Tabebuia serratifolia* (Vahl) G.Nicholson - *Protium guianense* (Aubl.) Marchand and *Peltogyne floribunda* (Kunth) Pittier/*Tabebuia serratifolia*-*Protium guianense* associations. In the west, particularly on the Chaguaramas peninsula, the DSF is of the *Machaerium biovulatum* Micheli - *Lonchocarpus punctatus* Kunth - *Bursera simaruba* (L.) Sarg. association. In either case, the canopy is low (3-10 m), epiphytes scarce, and seasonal drought lasts for approximately five months.

In the easterly part of the Central Range that includes Tamana and Mount Harris, *Aniba panurensis*/A. *citrifolia* - *Carapa guianensis* - *Eschweilera subglandulosa* (Steud. ex O.Berg) Miers/*Pentaclethra macroloba*/*Attalea maripa* (Aubl.) Mart. ESF occurs. Further south-west this is replaced by another ESF association, *Carapa guianensis* - *Pachira insignis* (Sw.) Savigny - *Eschweilera subglandulosa*/*Pentaclethra macroloba*/*Sabal* spp. These ESF formations are surrounded by a matrix of young secondary forest and teak plantations (*Tectona grandis* L.f.). Pittendrigh (1948) measured the diurnal progression of vertical gradients in temperature and humidity within *Carapa-Eschweilera* ESF at Tamana in August 1945. Near the forest floor, relative humidity (RH) was constantly near-saturating, whereas at 65 feet (19.8 m) RH fell from 100% at night to 85% at 3pm. Air temperature also showed a slightly stronger diurnal rhythm higher in the canopy, peaking during the middle of the day.

Beard (1944) noted that the climate of Tobago is reminiscent of that of the Toco district of Trinidad (in the northeast corner of that island). He suggested that a key distinction when compared with the rest of Trinidad is that whereas there the period of maximum rainfall occurs in August, in Toco and Tobago it occurs after the *petit carême*, in November. This could explain the observation that during field surveys conducted in September 2016, extremely few inflorescences or infructescences of any *Aechmea* species were observed outside of the northeast, whereas in the northeast *Ae. aquilega* and especially *Ae. dichlamydea* were in full flower at multiple locations. The period of heaviest rainfall

seems to be coincident with the disintegration of matured infructescences. For the Main Ridge of Tobago, Beard proposes a mean annual rainfall of over 3810 mm. Seasonal drought is more severe in Tobago than in Trinidad, and Beard thought the humidity to be generally lower and the winds more constant, increasing the evaporative demand. Beard identified three types of rain forest on Tobago, two of which are strongly determined by edaphology: Lowland Rain Forest (LRF; *Carapa guianensis* - *Andira inermis* (Wright) DC.), with an upper limit of 250-370 m; Lower Montane Forest (LMF; *Byrsonima spicata* - *Licania biglandulosa*), occurring above LRF on schist; and Xeric Rain Forest (XRF; *Manilkara bidentata* - *Guettarda scabra* (L.) Vent.), occurring above LRF on igneous soils. DSF (*Bursera simaruba*-*Lonchocarpus domingensis* (Pers.) DC.) and littoral and mangrove formations are also present. According to the estimations of land cover based on satellite imagery made by Helmer et al. (2012), approximately 84% forested of Tobago is currently forested, although this includes extensive tracts of invasive bamboo.

Appendix 6.6

A6.6.1 General observations from transects

Some general observations of the relationships between bromeliad distributions and forest structure and composition were made during field surveys. Patches of forest with abundant lianas typically harboured few epiphytic bromeliads, and very few were observed in palm-dominated forests. Only isolated individuals of *Guzmania monostachia* (L.) Rusby ex Mez, and no *Aechmea* bromeliads, were seen growing on bamboo. Epiphytes tended to occur in greater abundance in the vicinity of streams and seepages, where the ambient humidity was higher. This was especially true of the gallery forests south of the St David's Ridge in the Matura Forest area. Epiphytic bromeliad mortality was observed in a few instances of recent ground fire events, including on the north face of Morne Catherine.

Terrestrial individuals of *Ae. aquilega* were frequent in certain localities, being particularly abundant in the vicinity of the Hollis Reservoir. A few terrestrial individuals of *Ae. fendleri* were seen in montane forest, but these were generally much rarer and most appeared to be the result of branch-falls. Individuals of all *Aechmea* species showed a high degree of phenotypic plasticity, particularly with respect to foliar morphology and pigmentation. Shaded individuals tended to display longer, narrower leaves with reduced marginal spines, whereas exposed individuals had shorter, broader leaves with more pronounced spines and higher anthocyanin content. Plasticity was especially marked in *Ae. nudicaulis*, in which the morphology of the rosette varied from a tight tubular structure in exposed individuals to a lax arrangement with a high proportion of horizontal leaf surfaces in the most shaded individuals.

More detailed descriptions of field observations are given below, by area as shown in Fig. A6.6.1.

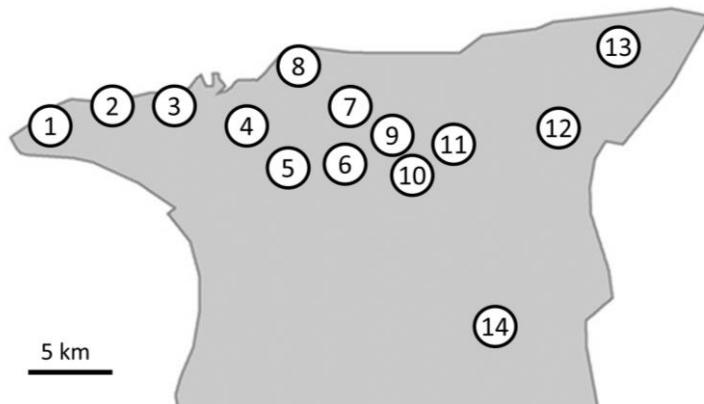

Figure A6.6.1. Distribution of geographical areas discussed in this appendix.

(1) Chaguaramas Peninsula

Towards the western end of the Chaguaramas peninsula (see Fig. 6.3.1 for geographical locations discussed throughout this section), *Ae. aquilega* and *Ae. nudicaulis* were common near sea-level in the vicinity of Chaguaramas and Point Gourde, as well as along the floor of the Tucker Valley up to Macqueripe. Although the ESF on the flanks of Morne Catherine (539 m) was generally dry, rich in lianas and poor in epiphytes, several clones of *Ae. aquilega* and *Ae. nudicaulis* were observed in the summit cap of LMF.

(2) North coast between Chaguaramas Peninsula and Diego Martin

Between Macqueripe at the head of the Tucker Valley and North Post at the head of the Diego Martin Valley only *Ae. nudicaulis* occurred (at low density) in the dry coastal forest composed of palms and *Ficus* spp. near Corozal Point. Above this, on the ridge of Pierre Knoll (ca. 500 m), no *Aechmea* bromeliads were observed, despite the presence of several high-density populations of *Lutheria splendens* in well-developed LMF. *Ae. aquilega* and *Ae. nudicaulis* occurred through the Diego Martin Valley as well as through the Morne Coco Valley. Only *Ae. nudicaulis* was observed above Port-of-Spain near Fort George, but *Ae. aquilega* occurred with *Ae. nudicaulis* on isolated trees throughout Port-of-Spain and Maraval.

(3) North coast between Diego Martin and Maracas Bay

Ae. fendleri was present alongside *Ae. aquilega* and *Ae. nudicaulis* in isolated trees at the top of the Fond Pois Doux Road (ca. 620 m) above St Cite Bay. *Ae. fendleri* was also observed in coastal LMF running down towards Paragrant Bay. Between La Vache Bay and Balata Bay, *Ae. fendleri* occurred on a N-S spur of the Main Ridge, with *Ae. aquilega* occurring around the Maracas Lookout below. Another large population of *Ae. fendleri* was found on the northern side of the col over the Main Ridge between Maracas Bay and the Santa Cruz Valley.

(4) Saddle Road, Santa Cruz Valley, Maracas Valley and El Tucuche

Ae. aquilega and *Ae. nudicaulis* were observed throughout the Saddle Valley and Santa Cruz Valley, as well as the La Canoa Valley, which branches off the latter. The same species were abundant in the Maracas Valley. Above Loango, near the head of this valley, *Ae. fendleri* was observed at 440 m and above, as was the case on a separate transect along the Hobal trail to the summit of El Tucuche. *Ae. fendleri* was observed in LMF on the northern side of the col from Loango to Las Cuevas until the trail dropped below 460 m. A second route to El Tucuche along the Old Road from the Bancal Road above Caurita provided numerous observations of *Ae. fendleri* and *Ae. nudicaulis* in LMF and MF

above 480 m. The southern portion of the ridge between the Santa Cruz and Maracas Valleys culminates in a summit of ca. 700 m. While the forest on the eastern (Maracas Valley) side has been largely destroyed, it remains intact on the western (Santa Cruz Valley) side, as well as along the top of the ridge. *Ae. fendleri* was observed above 600 m, while the highest specimen of *Ae. aquilega* observed on the western side occurred at 360 m.

(5) *Mount Tabor, Caura Valley and Lopinot Valley*

On the Mount Tabor/Mount St Benedict massif, only *Ae. nudicaulis* was observed throughout both the dry, palm-dominated secondary forest and the LMF at higher elevations. This was despite the presence of *Lutheria splendens*, a marker of wet LMF and MF generally found to co-occur with *Ae. fendleri* alongside a typical ground flora including *Renealmia thyrsoidea* (Ruiz & Pav.) Poepp. & Endl. (Zingiberaceae), *Prestoea pubigera* (Griseb. & H.Wendl.) Hook.f ex Benth. & Hook.f (Arecaceae), and bryophytes such as *Leucobryum* sp. (Dicranaceae). The degree of disturbance at lower elevations may explain the apparent absence of *Ae. aquilega*; much of the vegetation consisted of razor-sedge, bamboo or burnt ground, with only a few scattered mature trees rich in lianas. *Ae. aquilega*, alongside *Ae. nudicaulis*, was nevertheless abundant along the floor of the Caura Valley. At the head of this valley, *Ae. fendleri* was observed below the Main Ridge at 420 m. The bromeliad flora followed roughly the same elevational pattern in the adjacent Lopinot Valley, with *Ae. aquilega* and *Ae. nudicaulis* along the valley floor and *Ae. fendleri* observed at the head of the valley from 500 m upwards. *Ae. fendleri* may have been able to survive slightly lower than this, but there was much clearance for cultivation in the upper Lopinot Valley. The highest point of the southern portion of the ridge between the Lopinot and Caura Valleys was approached from the Lopinot side, with the highest *Ae. aquilega* being observed at 440 m and *Ae. fendleri* above 560 m.

(6) *Arima Valley*

Ae. aquilega and *Ae. nudicaulis* were abundant in the floor of the Arima Valley. A transect over the ridge to the Lopinot Valley found *Ae. fendleri* above 390 m and another transect onto the opposing ridge above the Simla Research Station found *Ae. fendleri* above 410 m. *Ae. fendleri* became abundant on the Arima-Blanchisseuse Road above the Asa Wright Nature Centre at ca. 400 m. *Ae. fendleri* and *Ae. nudicaulis* were observed in the LMF along the Main Ridge at the top of the Lopinot and Arima Valleys, and into the MF on Morne Bleu. They did not, however, occur in the MF near the summit of Morne Bleu (i.e. above 800 m).

(7) *Brasso Seco and Morne La Croix*

On the north face of the Main Ridge beyond the Arima-Blanchisseuse Road col, *Ae. fendleri* transitioned into *Ae. aquilega* along the Paria-Morne Bleu Road at ca. 400 m. *Ae. aquilega* was abundant around Brasso Seco village. One isolated rosette of *Ae. fendleri* was observed along the Paria Bay trail from Brasso Seco. Three transects from Brasso Seco up onto the north face of the Main Ridge identified a transition from *Ae. aquilega* to *Ae. fendleri* between 280 m and 400 m. Along the Madamas Road, which follows a valley directly below the Main Ridge directly eastwards from Brasso Seco, *Ae. aquilega* and *Ae. nudicaulis* were abundant. One *Ae. fendleri* rosette was recorded at 180 m, and two transects along riverbeds leading up towards the Main Ridge identified a transition to *Ae. fendleri* dominance at 250 m. A transect from Morne La Croix up towards the Main Ridge above the head of the Caura Valley located the transition to *Ae. fendleri* in LMF at 340 m. *Ae. aquilega* and *Ae. nudicaulis* both occurred frequently along the Brasso Seco-Paria trail, and in the drier forest on a ridge of 340 m adjacent to this trail, only *Ae. aquilega* was observed.

(8) Blanchisseuse and Las Cuevas

Both *Ae. aquilega* and *Ae. nudicaulis* occurred around Blanchisseuse and along the north coast to Las Cuevas. These species were also common in the Rincon Valley south of Las Cuevas Bay and up to the Rincon Waterfall. On the headland between Las Cuevas and Maracas Bay, *Aechmea* bromeliads were absent.

(9) Heights of Guanapo, La Laja and El Cerro del Aripo

Both *Ae. aquilega* and *Ae. nudicaulis* occurred along the floor of the Heights of Guanapo. Transects between the bottom of the valley and La Laja (the col on the Main Ridge between Morne Bleu and El Cerro del Aripo) identified the transition from *Ae. aquilega* to *Ae. fendleri* at ca. 300 m. *Ae. fendleri* was abundant and *Ae. nudicaulis* was also observed as El Cerro del Aripo was approached from La Laja. However, in MF above 800 m, neither of these species was recorded. Above 860 m, *Ae. aripensis* was seen, including one rosette on the summit itself (940 m).

(10) Heights of Aripo and Chaguaramal

Ae. aquilega and *Ae. nudicaulis* were both common in the floor of the Heights of Aripo. Along the trail to the summit of Chaguaramal, the transition from *Ae. aquilega* to *Ae. fendleri* occurred at ca. 350 m. Above this, *Ae. fendleri* was abundant to the summit (859 m). On the eastern side of the Heights of Aripo, a transect onto the ridge below Morne Poui identified a transition from *Ae. aquilega* to *Ae. fendleri* at ca. 320 m.

(11) Hollis, Cumaca and Platanal

Along the road from Valencia to the Hollis Reservoir, *Ae. aquilega* and *Ae. nudicaulis* occurred frequently. At the dam (ca. 200 m), There were several rosettes of *Ae. fendleri* in isolated trees, alongside both *Ae. aquilega* and *Ae. nudicaulis*. Between the reservoir and the Morne Pouï ridge, *Ae. fendleri* was common, and isolated rosettes of *Ae. aquilega* occurred up to 260 m. On the Cumaca Road to the east of Hollis, *Ae. aquilega* occurred at elevations up to 400 m, while *Ae. fendleri* was observed up to 440 m. Notably, *Ae. fendleri* occurred down to 115 m near the Oropouche River. *Ae. nudicaulis* was common throughout. At Platanal, below the St David's Ridge, only *Ae. nudicaulis* was recorded, although *Ae. dichlamydea* was observed at two locations on a spur of the St David's Ridge.

(12) Matura forest region

Ae. aquilega, *Ae. dichlamydea*, and *Ae. nudicaulis* all occurred around the estuary at Saline Bay, and were observed up to the margins of the monospecific mora forest, after which *Ae. aquilega* was no longer recorded. Along the Rio Seco (a major river in the mora forest), *Ae. nudicaulis* was frequent, and *Ae. dichlamydea* was occasionally observed. Transects between Gray Trace (Salybia) and Fig Walk River and between Mora Trace (Matura) and a ridge at ca. 250 m and 2 km east of Cumaca yielded similar results.

(13) Redhead-Matelot

Ae. aquilega and *Ae. nudicaulis* were abundant around the north-east coast between Redhead and Matelot. Several transects inland (Ravin Anglais, Grand Fond from L'Anse Noire, and inland from Sans Souci, Grande Riviere and Matelot) provided further records of these species as well as *Ae. dichlamydea*. *Ae. fendleri* was not observed in this region.

Along a N-S transect starting from the Dass Estate (Grande Riviere), *Ae. nudicaulis* and *Ae. dichlamydea* occurred infrequently, with high-density populations of *L. splendens* in the wetter areas of forest. No epiphytic bromeliads were observed in the dry secondary vegetation around Galera Point, a low-lying area formerly occupied by extensive coconut palm plantations.

(14) Central Range and South

In the Central Range, transects across Mount Tamana and Brigand Hill did not produce any observations of *Ae. fendleri*, and *Ae. aquilega* and *Ae. nudicaulis* were abundant from the base to the summit. In South Trinidad, transects along Saunders Trace (Rio Claro-Preau) and Edward Trace (Penal Rock-Guayaguayare) showed *Ae. aquilega* and *Ae. nudicaulis* were abundant through various types of lowland seasonal forest and plantations throughout this region. By contrast, almost no epiphytic bromeliads occurred in the palm-dominated vegetation of the east coast between La Savanne and Manzanilla Bay.

Appendix 6.7

A6.7.1 Forecasting future potential distributions

Forecast future potential distributions were projected for each species and geographical region. Forecasting was performed in MaxEnt using the same bioclimatic variables (MAT, DTR, MAP, P_{seas} , P_{dry}) estimated at 30 arc-second resolution for the year 2070 using the CCSM4 General Circulation Model and assuming the representative concentration pathway rcp85. This rcp was selected because it is a ‘worst-case scenario’ that should highlight the maximal potential effect of anthropogenic emissions on species distributions by the late 21st century. The 2070 bioclimate rasters for each region are displayed in Appendix 6.3. Other climatic layers estimated using comparable methods were not available, and vegtype, altitude, slope and aspect were not included in the model for forecasting because of the possibility that the nature of interactions between bioclimatic layers and these variables could differ significantly under the 2070 scenario.

Under the 2070 climate scenario, the area of suitable environmental space for *Ae. aquilega* is not expected to change considerably on Trinidad (Fig. A6.7.1a). There is a projected increase in P_{occ} at higher elevation in the Northern Range, and a slight diminution in P_{occ} across the lowland areas of the island. On Tobago, the improvement of environmental suitability along the Main Ridge is noticeable (Fig. A6.7.1b), and the same effect is in evidence in the projection for the Paria Peninsula (Fig. A6.7.1c).

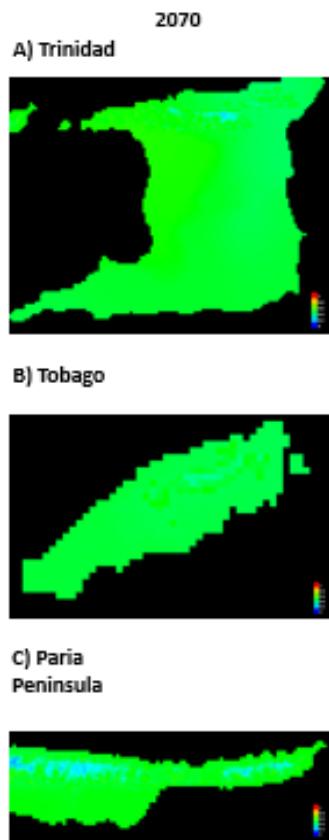

Figure A6.7.1 Projected probability distribution grid maps for *Ae. aquilega* under the rcp85 2070 climate scenario for a) Trinidad, b) Tobago and c) the Paria Peninsula.

There is a slight loss of projected P_{occ} for *Ae. dichlamydea* in northeast Trinidad under the 2070 scenario, but P_{occ} is projected to remain at 0.50 across large parts of this region (Fig. A6.7.2a). A widespread reduction of P_{occ} for *Ae. dichlamydea* is projected to occur across Tobago under the 2070 scenario, although P_{occ} is projected to remain above 0.60 across large areas in central and northern Tobago (Fig. A6.7.2b). P_{occ} is projected to decline substantially across the Paria Peninsula, with suitable environmental space contracting to the highest areas of the mountain chain (Fig. A6.7.2c).

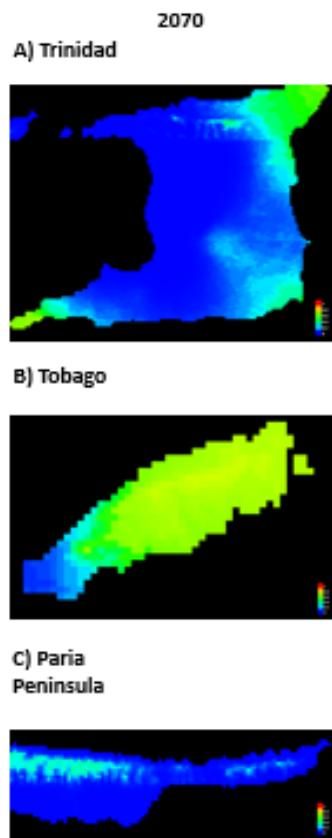

Figure A6.7.2 Projected probability distribution grid maps for *Ae. dichlamydea* under the rcp85 2070 climate scenario for a) Trinidad, b) Tobago and c) the Paria Peninsula.

The projected distribution of P_{occ} for *Ae. fendleri* in 2070 under the rcp85 scenario suggested a considerable reduction in the species' potential range in Trinidad (Fig. A6.7.3a). Only a few small patches of relatively low P_{occ} (~ 0.30) were projected on the Tucuche and Aripo massifs. Projected P_{occ} under the 2070 scenario was effectively zero across the whole of Tobago (A6.7.3b). A few patches with $P_{occ} \sim 0.30$ were projected to remain on the Paria Peninsula (Fig. A6.7.3c).

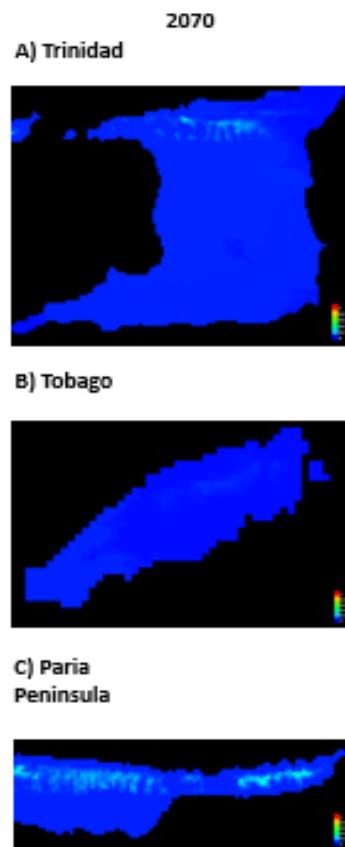

Figure A6.7.3 Projected probability distribution grid maps for *Ae. fendereri* under the rcp85 2070 climate scenario for a) Trinidad, b) Tobago, and c) the Paria Peninsula.

The projected 2070 suitability for *Ae. nudicaulis* of the northeastern and southwestern corners of Trinidad (Fig. A6.7.4a) and the southern plain of the Paria Peninsula (Fig. A6.7.4c) is slightly reduced ($P_{occ} = 0.20-0.40$), whereas in Tobago there is less of an effect (Fig. A6.7.4b).

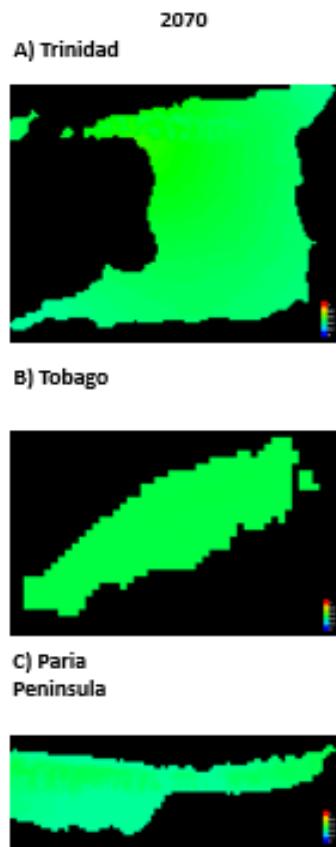

Figure A6.7.4. Projected probability distribution grid maps for *Ae. nudicaulis* under the rcp85 2070 climate scenario for a) Trinidad, b) Tobago and c) the Paria Peninsula.

Projection of bioclimatic envelope migration is contingent upon many assumptions, and should always be interpreted with care (Pearson and Dawson, 2003; Hijmans et al., 2006). However, the attempt to make projections for these species here was spurred on by the observation made during field surveys that *Ae. fendleri* was now absent on Tamana, the highest summit of the Central Range, where it had previously been recorded (Appendix 6.2). When considered alongside anecdotal and published evidence of changing precipitation and temperature regimes in Trinidad (Singh, 1997a, 1997b; Stephenson et al., 2014; Beharry et al., 2015; Jones et al., 2016), this suggests that climate change could already be having an impact on bromeliad species distributions. This would be consistent with the often-discussed potential of vascular epiphytes as climate change indicator species (Lugo and Scatena, 1992; Benzing, 1998; Nadkarni and Solano, 2002; Zotz and Bader, 2009; Hsu et al., 2012). Recent climate modelling studies have projected changes in temperature regime and a potential reduction of May-October precipitation of up to 35% across the Caribbean by 2071-2100 (Campbell et al., 2011; Hall et al., 2013; Taylor et al., 2013), and the impact of climate change on species' ecophysiological performance and the geographical distribution of potential niche space is likely to intensify.

The projections produced using the SDMs elaborated here suggest that, under the assumptions of the rcp85 scenario and CCSM4 GCM, by 2070 there could be a complete loss of suitable climate space for *Ae. fendleri* in both the Northern Range of Trinidad and the Paria Peninsula. Although the species occurs in a few other scattered localities along the Coastal Cordillera of Venezuela, these populations occupy the same bioclimatic envelope and may therefore suffer a similar loss of suitable habitat. In the Trinidadian context, the projections hint at a minimal enhancement of the suitability of some adjacent low-elevation regions by 2070, but since this effect is so small and much of this area is subject to extensive human disturbance, it is unlikely to provide alternative habitat for *Ae. fendleri*. If these projected climatic changes do occur in Trinidad and *Ae. fendleri* cannot show sufficiently rapid acclimation or adaptation, it is therefore highly likely that the species will go locally extinct, with similar outcomes being probable for mainland populations.

Climate change is expected to have a particularly strong impact on tropical montane forest diversity and function (Foster, 2001; Nadkarni and Solano, 2002), and the results of this investigation demonstrate how this could operate the species-level. Trait-mediated physiological sensitivity to climatic factors defines the narrow geographical ranges of species such as *Ae. fendleri*, which may promote niche segregation and species coexistence across topographically and climatically complex landscapes, but increase species' vulnerability to rapid change in the environment. Upslope extinction chains are therefore likely consequences of climate change on tropical mountain ranges (Raxworthy et al., 2008; Jump et al., 2012), especially given the probable migration lag (Corlett and Westcott, 2013). Current protected area networks may be of little use in mitigating this effect (Ponce-Reyes et al., 2012). Unlike in high elevation continental cordilleras such as the Andes, where thoughtful land-use policies could assist upslope migration of forest species as climate change effects advance (Feeley and Silman, 2010), in Trinidad there is no possibility of upslope migration because of the small stature of the Northern Range.

None of the *Aechmea* species discussed here has been assessed for conservation status by the International Union for the Conservation of Nature (IUCN, 2016). The results of species distribution projection for the 2070 rcp85 scenario suggest that the location and extent of bioclimatically suitable areas of Trinidad and Tobago for these species could be subject to extreme change by the end of this century, with *Ae. fendleri* likely to lose as much as 100% of its environmentally suitable habitat on Trinidad. *Ae. dichlamydea* var. *trinitensis*, is also likely to be negatively impacted, which may be of special concern since this taxon is endemic to Trinidad and has already suffered extensive loss of habitat through the conversion of large areas of mora forest around Matura to coniferous forestry plantations. At least in qualitative terms, these projections should be taken into account by policy-makers designing measures for the future conservation of Trinidad's fragile natural heritage.

Appendix 6.9

A6.9.1 Additional factors possibly involved in *Aechmea* niche differentiation

Implicit in the work presented here is the assumption that physiological factors are major drivers of the distributions of bromeliad species in Trinidad. The clear relationships between the distributions of *Ae. aquilega*, *Ae. dichlamydea* and *Ae. fendleri* and climatic variables demonstrated in our presence data are consistent with this assumption, and the corresponding divergences in environmental tolerances between the species uncovered by physiological characterisation make this case highly compelling. However, it is important to note that alongside these interactions with abiotic factors, biotic considerations could also play a role in shaping regional species distributions. Two key phenomena which could be involved, pollination and dispersal, are briefly discussed here. Only sporadic reports are available from which to piece together a picture of the pollination biology of the Trinidadian bromeliads. Snow and Snow (1972) reported that floral visitors of *Ae. fendleri* include the copper-rumped hummingbird (*Amazilia tobaci* Gmelin) and the rufous-breasted hermit (*Glaucis hirsutus* Gmelin). The same authors observed visits to *Ae. dichlamydea* by the same species, while *Ae. nudicaulis* was frequented by *A. tobaci*, the white-chested emerald (*A. brevirostris* Lesson) and the little hermit (*Phaethornis longuemareus* Lesson). *Ae. aquilega* was visited by the widest range of species: *A. brevirostris*, *A. tobaci*, *G. hirsutus*, *P. longuemareus* and the green hermit (*P. guy* Lesson). In a study conducted in the forest of Cerro Copey on Isla Margarita (Venezuela), de Enrech and Madriz (1994) recorded pollination of *Ae. fendleri* by unspecified birds, and a butterfly of the nymphalid genus *Caligo* Hübner (owl butterflies). *Ae. nudicaulis* was the most generalist bromeliad in terms of pollination in a study by Piacentini and Varassin (2007) in southern Brazil. More generally, prezygotic barriers appear to be very weak between many bromeliad species (Wendt et al., 2008). Although it is far from possible to provide a comprehensive description of the pollination biology of the Trinidadian *Aechmea* species, the observations of relatively relaxed pollination syndromes and the sharing of widely-distributed pollinators suggest that the availability of pollinators is unlikely to be a significant factor in shaping the distributions of these bromeliads in Trinidad.

Seed dispersal is even less well documented than pollination. During the course of the field surveys made during this investigation, observations were made of visits to infructescences of *Ae. fendleri* by the bearded bellbird (*Procnias averano* Hermann). Although feeding was not directly observed, the baccate fruits of *Ae. fendleri* may well represent an attractive nutritional resource. The distinctive call of *P. averano* was often heard in areas of forest where *Ae. fendleri* was present, and never where *Ae. fendleri* was absent. It is possible that *P. averano* and/or other avian dispersers are at

least partly responsible for the distribution pattern of *Ae. fendleri* in the Northern Range. The apparent bioclimatic restriction of *Ae. fendleri* could in fact reflect a strongly-defined thermal niche of an avian disperser engendering biotic dispersal limitation. In a thesis on frugivory and dispersal in Tobagonian rainforest plants, Lefevre (2008) described *Ae. dichlamydea* var. *dichlamydea* as bird-dispersed, without providing any further information. *Ae. nudicaulis* fruits have been reported as eaten by tanagers (Thraupidae) in the Brazilian restinga (Gomes et al., 2008) and by ants in the Atlantic Forest (Pizo and Oliveira, 2000).

An additional autecological consideration that may be of great consequence but could not be included in this investigation is the role of the regeneration niche. Specifically, germination requirements and seedling ecophysiology could differ between species in ways that cannot be predicted from observations of the ecophysiological characteristics of mature plants, as discussed in **Chapter 2**. A recent and extensive survey of thermal niche breadth and optima for germination among bromeliads was carried out by Müller et al. (2016). Six *Aechmea* species were included in their analysis. None of these species occur on Trinidad, but they provide useful context. Thermal optima for germination in these species range from approximately 28°C to 35°C, and while the thermal niche breadth spanned at least 20°C in *Ae. melinonii* (subg. *Aechmea*, alongside *Ae. aquilega* and *Ae. fendleri*), it was less than 5°C in *Ae. racinæ* (subg. *Lamprococcus*). Therefore there appears to be considerable interspecific variation in thermal regeneration niche, and no inferences can as yet be drawn regarding the likelihood of thermal regeneration niche being an important factor in the distributions of the Trinidadian species. No specific information is available on germination in *Ae. fendleri* or *Ae. aquilega*. In the field, very dense populations of seedlings of both species are often observed in the thick bryophyte mats that frequently occur on the lateral branches of cocoa trees in abandoned plantations. These bryophyte mats are strongly retentive of moisture, and water limitation could therefore be an important driver of seedling mortality (Winkler et al., 2005). Some studies have looked at germination in *Ae. nudicaulis*. In this species, germination is positively photoblastic (Pinheiro and Borghetti, 2003; Marques et al., 2014), and shows a temperature optimum of approximately 25°C (Pinheiro and Borghetti, 2003). In the coastal restinga vegetation of southeastern Brazil, *Ae. nudicaulis* seedlings are highly susceptible to water and temperature stress (Mantovani and Iglesias, 2008). Overall, it is probable that species-specific requirements for germination and seedling establishment do play a role in environmental filtering and consequently on species distributional patterns, but these processes probably operate at a very fine spatial scale and are unlikely to account for the macro-scale differentiation in environmental distributions seen in the epiphytes. More detailed demographic and *in situ* physiological studies could be pursued over longer time periods to determine the susceptibility of individuals of different growth stages to

environmental stressors and the contribution of mortality at each of these stages to spatial population structure.
