Abstract

Adipocytes are one of the major stromal cell components of the human breast. These cells play a key role in the development of the gland and are implicated in breast tumorigenesis. Frequently, directional stromal collagen I fibres are found surrounding aggressive breast tumours. These fibres enhance breast cancer cell migration and are associated with poor patient prognosis. We sought to recapitulate these stromal components *in vitro* to provide a 3D model comprising human adipose tissue and anisotropic collagen fibres. We developed a human mesenchymal stem cell (hMSC) cell line capable of undergoing differentiation into mature adipocytes by immortalising hMSCs, isolated from breast reduction mammoplasties, via retroviral transduction. These immortalised hMSCs were seeded in engineered collagen I scaffolds with directional internal architecture and adipogenesis was chemically induced, resulting in human adipose tissue being synthesised *in vitro* in an architectural structure associated with breast tumorigenesis. Subsequently, fluorescently labelled **from an established breast cancer cell line** were seeded into this model, co-cultured for 7 days and imaged using multiphoton microscopy. Enhanced breast cancer cell migration was observed in the adipose-containing model over empty scaffold controls, demonstrating an adipocyte-mediated influence on breast cancer cell migration. Thus, this **3D *in vitro*** model recapitulates the migratory effects of adipocytes observed on breast cancer cells and **suggests that it could have utility with** fresh breast tumour biopsies as an assay for cancer therapeutic efficacy in personalised medicine strategies.

Introduction

The stromal extra-cellular matrix (ECM) at the periphery of breast tumours mainly comprises collagen I fibres that are organised in a number of so-called tumour-associated collagen signatures (TACS) [1]. One such signature, TACS-3, is characterised by aligned, or anisotropic, bundles of collagen fibres that are orientated perpendicular to the tumour boundary and this arrangement has been associated with poor patient prognosis [1,2]. We have developed a system that recapitulates the TACS-3 arrangement by synthesising 3D engineered collagen scaffolds with an anisotropic internal architecture [3].

During breast tumour progression, a variety of stromal cells contribute to the lethal metastatic spread of epithelial cancer cells to various organs [4]. One of the most abundant cellular components of the breast stroma is adipocytes and these cells have been implicated in tumour phenotype [5]. Through the synthesis and secretion of a variety of hormones and cytokines, including oestrogen, adipocytes communicate with breast epithelium [5]. It is therefore paramount that any model investigating breast cancer cell migration should incorporate adipocytes to provide a physiologically relevant setting.

Previous *in vitro* breast cancer models have frequently utilized the 3T3-L1 murine embryonic preadipocyte cell line to study adipocyte influences on cancer cell migration [6–8]. Although these models have provided important insight into cancer cell migratory potential, we sought to replace this murine cell line with a human alternative to more accurately recapitulate the human breast stroma. Human mesenchymal stem cells (hMSC) that have been isolated from donor tissue can be differentiated *in vitro* into mature adipocytes, making them an ideal candidate for this purpose [9]. Furthermore, hMSCs reside within the adult breast and can be

1
2
3 purified from breast reduction mammoplasty tissue, thus providing a more relevant cell type
4
5 [10].
6
7
8

9 According to an NC3Rs review, it is estimated that >100 million rodents per year are culled
10 worldwide for experimentation [11]. With a paradigm shift in opinions on animal testing
11 alongside obvious financial incentives, scientists are being encouraged to minimise *in vivo*
12 animal experimentation. Furthermore, there is a push to use 3D cell cultures as *in vitro*
13 models as they more accurately resemble the *in vivo* environment, in comparison with their
14 2D counterparts [12]. Using this ideology, this study aimed to recapitulate breast cancer cell
15 migration using 3D *in vitro* systems that only required cells from a human origin.

25

26 In this study, we initially set out to confirm if the previously described TACS-3 phenotype
27 could be observed in a human breast tumour sample utilising histological, optical clearing
28 and immunohistochemical approaches [1,2]. We then sought to immortalise hMSCs to
29 provide a human breast-derived cell line capable of undergoing adipogenesis to replace the
30 frequently used 3T3-L1 murine cell line and provide a humanised model. To generate adipose
31 tissue in an collagen structure relevant to breast cancer, immortalised hMSC were then
32 seeded into engineered collagen scaffolds with an anisotropic internal architecture [3] and
33 differentiated with an adipogenic cocktail [9]. Successful differentiation was confirmed using
34 immunolocalisation of mature adipocyte markers and specialised two-photon microscopy
35 techniques. Following this, fluorescently tagged MDA-MB-231 breast cancer cells were
36 seeded and their migration assessed. These data demonstrated a pro-migratory effect of
37 **human** adipocytes on **human** breast cancer cells within our 3D model.

Materials and methods

Masson's Trichrome

Human ER+ breast tumour biopsies were paraffin embedded and sections were bathed in the following reagents for the following lengths of time: 100% Xylene: 6mins twice, 100% ethanol: 3mins, 95% methylated spirit: 2mins, 70% methylated spirit: 2mins, running tap water: 5mins, Weigert's haematoxylin: 15mins, running tap water: 5mins, 1% hydrochloric acid in 70% ethanol (acid alcohol): 5s, running tap water: 5mins, red mixture: 5mins, rinsed in 0.2% glacial acetic acid, filtered orange mixture: 5mins, rinsed in 0.2% glacial acetic acid, 0.5g aniline blue in 0.2% glacial acetic acid: 2mins, rinsed in 0.2% glacial acetic acid/70% methylated spirit: 40s, 95% methylated spirit: 1min, 100% ethanol: 3mins and 100% Xylene: 3mins. Sections were then mounted in Sub-x and left to dry.

Whole human tumour fragment immunostaining using Cleared Unobstructed

Body Imaging Cocktails (CUBIC)

CUBIC was carried out according to a previously published protocol [13,14]. Human ER+ breast tumour biopsies were fixed overnight in 4% PFA at 4°C followed by immersion in Reagent 1a (modified from Reagent 1, unpublished, available at <http://cubic.riken.jp/>) at 37°C for three days changing into fresh Reagent 1a each day. Samples were blocked overnight in 0.5% Triton-X-10% NGS-PBS (blocking solution). Primary antibodies anti-K8 (DSHB, #TROMA-1, 1:150) and anti-ER α (Leica, #NCL-L-ER-6F11, 1:50) were diluted in blocking solution and agitated on a rocker for 5 days at 4°C. Samples were washed in PBS briefly followed by 3x1 hour washes in fresh PBS. Secondary antibodies goat anti-rabbit Alexafluor647 (LifeTech, #A21245, 1:500) and goat anti-rat (LifeTech, #A21247, 1:500) were diluted in blocking solution and agitated on a rocker for 2days at 4°C. Samples were washed in PBS briefly followed by a 1hour wash in fresh PBS. Nuclei were marked with a

1
2
3 2hour wash in 10 μ M DAPI. Samples were washed in PBS briefly followed by a 1hour wash
4
5 in fresh PBS and immersed in Reagent 2 at 37°C in a dry incubator for 24hours before
6
7 imaging [13–15]. Two-photon microscopy techniques were carried out on a LaVision BioTec
8
9 TriM Scope II upright 2-photon scanning fluorescence microscope.

31 32 **Human primary mesenchymal stem cells (MSC)**

33 34 **Maintenance**

35
36 Human mesenchymal stem cells (hMSC) isolated from routine breast reduction
37
38 mammoplasty surgery (passage 0) were provided by Professor Mohamed Bentires-Alj
39
40 (Universität Basel, Switzerland). hMSCs were maintained in MSC MM (DMEM/F12
41
42 supplemented with 20% FCS, 15mM HEPES (Sigma #83264), 1nM 17- β -estradiol (Sigma
43
44 #E2758), 100U/ml P/S, 50 μ g/ml gentamicin (Sigma #G1397), 10ng/ml EGF, 10ng/ml bFGF
45
46 (Peprotech #100-18B). Cells were passaged at approximately 70% confluency, ensuring that
47
48 100% confluency was not reached during passage steps to avoid spontaneous differentiation.

60

Adipogenesis

hMSC grown to 100% confluency had their MSC MM removed and replenished with MSC adipogenic media (DMEM/F12 supplemented with 10% FCS, 15mM HEPES, 10nM 17- β -estradiol, 100U/ml P/S, 50 μ g/ml gentamicin, 5 μ g/mL insulin, 1 μ M dexamethasone, 0.5 mM IBMX, 60 μ M indomethacin (Sigma #I7378)). Media was replaced with fresh MSC adipogenic media every 48 hours for 11 days.

Antibiotic titration

Primary hMSCs were treated with puromycin (Gibco #A11138) in the range 0-1 μ g/ml or geneticin (Gibco #10131) in the range 0-600 μ g/ml in MSC MM for 5 days to determine the minimum concentration of each antibiotic required to kill 100% of cells (Supplementary Table 1).

Human embryonic kidney 293T (HEK293T) cells

HEK293T cell maintenance media (HEK293T MM) comprised DMEM (Gibco #41965) supplemented with 10% FCS. Cells were passaged at 70-90% confluency. Cells were obtained from ATCC and were kept below passage 15.

MDA-MB-231 cells

MDA-MB-231 cells were maintained in DMEM supplemented with 10% FCS. Cells were passaged at 70-90% confluency. Cells were obtained from ATCC and were kept below passage 15. Cell lines in our laboratory are routinely tested for mycoplasma contamination.

Retroviral transduction of human mesenchymal stem cells (hMSC)

HEK293T cells were transfected using the PEI method for lentiviral transfection [16] with the exception of using 3 μ g of viral DNA (retroviral plasmids pLXSN-neo-E6E7 and pBABE-puro-hTERT were gifted by Dr. Heike Laman (University of Cambridge, Department of Pathology)) and 2 μ g of envelope vector pMD2.G.. Virus-containing media

1
2
3 was supplemented with MSC MM in a 1:1 ratio. Following transduction MSCs were
4
5 passaged to remain sub-confluent. Transduced cells were selected by treatment with 600
6
7 $\mu\text{g/ml}$ geneticin (pLXSN-neo-E6E7) or 1 $\mu\text{g/ml}$ puromycin (pBABE-puro-hTERT) for 5 days
8
9 (Supplementary Table 2). Surviving cells were then pooled into smaller wells to increase cell
10
11 density and expanded for future use.
12

13 14 **Senescence-associated β -Galactosidase staining**

15
16 hMSC were seeded in 6 well culture plates and cultured until approximately 70% confluent.
17
18 Media was removed and cells were washed with PBS before fixing with 4% PFA at room
19
20 temperature for 15 mins. Cells were then washed twice with PBS and covered with β -
21
22 galactosidase staining solution (β -Galactosidase staining kit, Cell Signalling #9680). Plates
23
24 were then sealed with parafilm and incubated at 37°C in a dry incubator overnight. Cells
25
26 were imaged under a light microscope. Senescent cells stain positively for β -galactosidase
27
28 and appeared a blue/green colour.
29
30
31

32 33 **Immunocytochemistry (ICC)**

34
35 hMSC were cultured on glass coverslips and fixed in 4% PFA for 10mins. Permeabilization
36
37 was carried out for 15mins in 0.5% Triton-X-PBS (VWR chemicals #28817.295) followed by
38
39 1hour blocking in normal goat serum (NGS). Primary antibodies anti-laminin (Abcam,
40
41 #ab11575, 1:500), anti-collagen IV (Abcam, #ab6586, 1:500) or anti-Ki67 (Abcam,
42
43 #ab15580, 1:100) were added and left overnight at 4°C. Secondary goat anti-rabbit
44
45 AlexaFluor488 (LifeTech, #A11008, 1:500) was added to all samples for 1 hour. DNA was
46
47 marked using DAPI and cells were visualized using epi-fluorescence.
48
49
50

51 52 **Oil Red O**

53
54 To prepare a stock Oil Red O solution, 0.5g Oil Red O (Sigma #O0625) was dissolved in
55
56 100ml isopropanol (5mg/ml), incubated at room temperature for 1hour, filtered through a 0.2-
57
58
59
60

1
2
3 mm filter and stored at room temperature. To prepare a working solution of Oil Red O, 6ml
4
5 of stock solution was mixed with 4ml distilled water, incubated at room temperature for
6
7 1hour and filtered through a 0.2 mm filter. Undifferentiated hMSCs, or hMSCs following
8
9 11days adipogenesis, had their media removed and gently washed twice in PBS. Cells were
10
11 fixed in 4% PFA at 4°C for 1hour followed by two more gentle washes in PBS. Oil Red O
12
13 working solution was added, ensuring the entire cell surface was covered and incubated for
14
15 15mins at room temperature. Cells were then rinsed with distilled water approximately 5
16
17 times (until the solution was clear) and left in distilled water for light microscope imaging
18
19 analysis.
20
21
22

23 **SDS-PAGE and western blotting**

24
25 Undifferentiated hMSCs, and hMSCs differentiated for 11 days, were collected in
26
27 radioimmunoprecipitation assay (RIPA) buffer. A bicinchoninic acid assay (BCA) was then
28
29 performed on an aliquot and 20 µg of protein was added per lane. Following electrophoresis
30
31 and membrane transfer, blots were blocked in 5% bovine serum albumin (BSA) (Acros
32
33 organics #240405000) in phosphate buffered saline-0.1% Tween-20 (PBST) for 1 hour.
34
35 Primary antibody perilipin (Cell signalling #3470, 1:1000) and loading control anti-GAPDH
36
37 (Abcam #ab9482, 1:10000) were diluted in 5% BSA-PBST, added to blots and left rocking
38
39 overnight 4°C. Blots were washed 3 times for 5 min in PBST, moved into 5% BSA-PBST
40
41 containing the secondary antibody horseradish peroxidase (HRP)-anti-rabbit (Dako #PO448,
42
43 1:4000) and rocked at room temperature for 1 hour. Blots were then developed using
44
45 enhanced chemiluminescence (ECL) (GE Healthcare #RPN2109) substrate and photographic
46
47 film.

Anisotropic collagen scaffold synthesis

Anisotropic collagen scaffolds were prepared according to a modification of our previously published method [3]. Briefly, 1wt% collagen slurry was homogenised and aspirated into scaffold moulds containing copper pins. Moulds were placed into a pre-cooled (-40°C) freeze-drier so that the copper pins were in direct contact with the metal shelf and thermally cycled. Following freeze-drying, scaffolds were removed and placed in cross-linking solution (70% ethanol, 33mM 1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide hydrochloride (Sigma #E6383) and 6mM *N*-hydroxysuccinimide (Sigma #130672)) for 30 mins with constant agitation on a rotating plate. Following cross-linking, the scaffolds were removed to fresh 70% ethanol and degassed under vacuum (approximately 10kPa) for 5mins. Samples were stored in 70% ethanol to ensure sterility until required.

Engineered human adipose model - E6/E7-hMSC seeding and differentiation

1×10^6 E6/E7-hMSC cells were seeded into anisotropic collagen scaffolds, cultured for 7 days and differentiated using MSC adipogenic media for 11 days, replenishing MSC adipogenic media every other day.

Whole scaffold immunostaining

The human adipose model was fixed overnight in 4% PFA at 4°C followed by blocking overnight in 0.5% Triton-X-10% NGS-PBS (blocking solution). Primary antibodies anti-perilipin (1:50), anti-laminin (1:100) and anti-collagen IV (1:100) were diluted in blocking solution and agitated on a rocker for 5 days at 4°C. Samples were washed in PBS briefly followed by 3x1hour washes in fresh PBS. Secondary antibody goat anti-rabbit Alexafluor488 (1:500) were diluted in blocking solution and agitated on a rocker for 2days at

1
2
3 4°C. Samples were washed in PBS briefly followed by a 1 hour wash in fresh PBS. Nuclei
4
5 were marked with a 2 hour wash in 10µM DAPI. Samples were washed in PBS briefly
6
7 followed by a 1 hour wash in fresh PBS before imaging. Two-photon microscopy techniques
8
9 were carried out on a LaVision BioTec TriM Scope II upright 2-photon scanning
10
11 fluorescence microscope.
12

13 14 15 **Lentiviral transduction of MDA-MB-231 cells**

16
17 5.84 µg pMD2.G envelope vector, 11.68 µg p8.91 packaging vector and 18.25 µg pCDH-
18
19 EF1-MCS-T2A-tdTomato lentiviral transfer vector (cloned by modifying the pCDH-EF1-
20
21 MCS-T2A-copGFP vector from System Biosciences (#CD521A-1)) were transfected into
22
23 HEK293T cells using the previously published polyethylenimine (PEI) method [16].
24
25 Following this, virus-containing media from HEK293T cells was collected and added with
26
27 4µg/ml polybrene to MDA-MB-231 cells 48 hours after transfection. MDA-MB-231 cells
28
29 were then spin transduced at 1800rpm for 45 mins at room temperature. This process of
30
31 collecting viral-media and spin transducing was repeated again 24 hours later. Transduced
32
33 MDA-MB-231 cells were then isolated by FACS and expanded in culture.
34
35

36 37 38 **Fluorescent activated cell sorting (FACS)**

39
40 tdTomato-expressing MDA-MB-231 cells were sorted using a MoJo cell sorter with the
41
42 assistance of Nigel Miller (University of Cambridge) based on their fluorescence. Non-
43
44 transduced MDA-MB-231 cells were used as a negative control.
45
46

47 48 **tdTomato-expressing MDA-MB-231 cell / human adipose model** 49 **migration assay**

50
51 Migration assays were carried out according to a modified previously published protocol [3].
52
53 Briefly, empty anisotropic collagen scaffolds and adipose invested collagen scaffolds were
54
55 placed into the upper wells of 6mm diameter Boyden chambers (0.4µm pore size, Costar
56
57
58
59
60

1
2
3 #3470) with upward facing seeding funnels. tdTomato⁺ MDA-MB-231 cells were trypsinized
4
5 and seeded into scaffold seeding funnels at a concentration of 5×10^6 cells/ml in a volume of
6
7 10 μ l. The bottom Boyden chamber was then filled with 750 μ l MSC MM and the scaffolds
8
9 incubated for 4 hours. Once the cells had attached to the funnel, the upper chamber was filled
10
11 with 250 μ l MSC MM. Samples were left to incubate for 7 days, with media changed every 48
12
13 hours. Following incubation, scaffolds were fixed for analysis in 4% PFA overnight at 4°C,
14
15 washed in PBS and divided in half through the nucleation point using a scalpel blade. Cell
16
17 nuclei were marked with SYTO16 (ThermoFisher #S7578) and samples were imaged using
18
19 multi-photon microscopy.
20
21
22

23 **Statistical analysis**

24
25 Statistical analysis of data was carried out using an unpaired one-way ANOVA with a Tukey
26
27 multiple comparisons test.
28
29
30

31 **Results**

32 **Human oestrogen receptor alpha (ER α) positive breast tumour biopsy displays a** 33 34 **tumour associated collagen signature-3 (TACS-3)**

35
36 To investigate the TACS-3 signature associated with poor patient prognosis [1,2] at an
37
38 increased level of detail, an ER⁺ breast tumour biopsy was analysed (Fig. 1). Following
39
40 surgery, the biopsy was fixed and bisected, with one half embedded in paraffin for
41
42 histological analyses and the other half processed for CUBIC optical clearing [14].
43
44
45
46
47
48
49

50
51 In order to visualise collagen, a Masson's Trichrome histological stain was employed (Fig.
52
53 1a). Directional anisotropic collagen fibres (Fig. 1a, arrows) were observed aligned
54
55 perpendicular to the periphery of the tumour, projecting between the adipocytes constituting
56
57
58
59
60

1
2
3 the surrounding fat pad (Fig. 1a, asterisks). Epithelial cells were observed in the tumour bulk,
4
5 on anisotropic collagen fibres at the tumour periphery and in the surrounding stroma (Fig.
6
7 1a), commensurate with a TACS-3 signature.
8
9

10
11 To investigate collagen structure in 3D, a CUBIC optical clearing protocol was utilised in
12
13 conjunction with immunostaining, to permit deep 3D imaging [14]. Stereoscopic visualisation
14
15 of the tumour following clearing revealed that CUBIC increased optical transparency
16
17 considerably (Fig. 1b). Collagen can be detected specifically without the need for staining by
18
19 using a non-linear imaging method called Second Harmonic Generation (SHG). Using second
20
21 harmonic generation (SHG) and two-photon fluorescence (2pf) microscopy, anisotropic
22
23 collagen fibres were observed running from right to left, between ER α ⁺/keratin-8⁺ (K8⁺)
24
25 epithelial cells, within the cleared tumour sample (Fig. 1c,d).

31

32 **Human mesenchymal stem cells (hMSCs) can be immortalised by retroviral** 33 **insertion of the E6/E7 genes but not the hTERT gene**

34
35
36 Successive experiments focussed on immortalising hMSCs isolated from a breast reduction
37
38 mammoplasty [10] via retroviral insertion of either human telomerase reverse transcriptase
39
40 (hTERT) or the human papillomavirus oncogenes E6 and E7. Both hTERT and E6/E7 have
41
42 been utilised previously to immortalise human primary cells for extended cell culture [17–
43
44 21].
45
46
47
48

49
50 Following retroviral transduction, non-transduced hMSC (control, named hMSC hereafter),
51
52 hTERT-hMSC and E6/E7-hMSC were investigated for the appearance of senescence, a
53
54 phenomenon common to primary cells that are not immortalised, using a β -galactosidase
55
56 staining protocol. These data showed a high proportion of hMSCs and hTERT-hMSC had
57
58
59
60

1
2
3 become senescent, whilst the majority of E6/E7-hMSC had escaped senescence (Fig. 2a,
4 arrowheads).

5
6
7
8
9 As immortalisation can increase proliferative capacity [22], IHC analysis for the proliferation
10 marker Ki67 was employed (Fig. 2b,c). Cell lines were analysed either at pre-confluency or
11 post-confluency plus 11 days adipogenesis. At pre-confluency, significantly more
12 proliferating E6/E7-hMSCs were observed compared to both hMSC and hTERT-hMSC (Fig.
13 2c). Since adipogenesis induces terminal differentiation, low proliferation rates were
14 observed after 11 days in adipogenesis medium as expected (Fig. 2b,c) [23,24].

24

25 **E6/E7-hMSCs successfully undergo adipogenesis in 2D culture**

26
27 In order to confirm that the cell lines could undergo differentiation into adipocytes following
28 11 days culture in adipogenic medium, lipid droplets were detected using the fat soluble dye
29 Oil Red O, which produces a red stain (Fig. 2d). Upon adipogenesis, both hMSC and E6/E7-
30 hMSC generated multiple lipid droplets in the cytoplasm of the majority of cells (Fig. 2d). In
31 contrast, hTERT-hMSC produced little or no detectable lipid droplets (Fig. 2d). To confirm
32 differentiation status at the molecular level, cell lysates were compared by western blotting
33 for the lipid vesicle membrane marker perilipin (Fig. 2e). In agreement with Fig. 2d,
34 differentiated hMSC and E6/E7-hMSC cells both expressed perilipin, whilst hTERT-hMSC
35 had undetectable levels (Fig. 2e).

44
45
46
47
48

49 Previously it has been reported that upon adipogenesis, both 3T3-L1 cells and MSCs
50 synthesise the basement membrane proteins laminin and collagen IV [25–28]. Therefore, we
51 next investigated their expression. Immunocytochemistry revealed a significantly increased
52 deposition of laminin and collagen IV in differentiated hMSC and differentiated E6/E7-
53
54
55
56
57
58
59
60

1
2
3 hMSC compared to their undifferentiated states (Fig. 3). In contrast, although increased
4
5 levels of laminin and collagen IV were present for differentiated hTERT-hMSC, these were
6
7 not statistically significant (Fig. 3).
8
9

10 11 12 **E6/E7-hMSC successfully undergo adipogenesis within anisotropic collagen** 13 14 **scaffolds** 15

16
17 Following successful immortalisation and adipogenesis of E6/E7-hMSC in 2D culture, this
18
19 cell line was selected as the candidate to generate a human adipose model. Subsequent
20
21 experiments investigated E6/E7-hMSC adipogenic capacity in 3D by seeding, culturing and
22
23 differentiating E6/E7-hMSC in anisotropic collagen scaffolds and has been shown
24
25 schematically in Fig 4a. Scaffolds were then fixed, bisected and 3D immunostained with anti-
26
27 perilipin antibodies to mark lipid vesicles. Confocal microscopy tile scans revealed that
28
29 differentiated E6/E7-hMSC with perilipin⁺ vesicles covered large areas of the scaffold's
30
31 internal architecture, thus indicating the presence of mature adipocytes (Fig. 4b).
32
33

34
35
36
37 To further confirm the presence of lipids and therefore adipocytes, multi-photon microscopy
38
39 and immunostaining techniques were employed (Fig. 4c). 2pf was used to image both DNA
40
41 and anti-perilipin antibody staining, SHG to image collagen I and coherent anti-raman
42
43 spectroscopy (CARS) to image lipids (Fig. 4c). CARS imaging is a revolutionary technique
44
45 capable of imaging tissue without the use of labels or dyes. This technique can yield
46
47 information about the distribution of specific cellular molecules by probing their vibrational
48
49 properties. As the CARS input signal was specifically adjusted to the molecular vibration of
50
51 lipids, the output signal therefore indicated the presence of lipids. These images showed that
52
53 E6/E7-hMSC attached to the inner surface of the anisotropic collagen I pores with perilipin⁺
54
55
56
57
58
59
60

1
2
3 vesicles containing an interior CARS signal (Fig. 4c). As a further confirmation of
4
5 differentiation, immunostaining in 3D for laminin and collagen IV was employed. Both
6
7 laminin and collagen IV expression were observed in all E6/E7-hMSC cells at a range of z-
8
9 depths within the collagen I scaffold (Fig. 4d,e). Taken together, these data demonstrated that
10
11 E6/E7-hMSC could successfully differentiate into mature adipocytes within anisotropic
12
13 collagen I scaffolds.
14
15
16
17
18
19

20 **E6/E7-hMSCs support the migration of MDA-MB-231 breast cancer cells**

21
22 Subsequent experiments aimed to evaluate whether the model could recapitulate breast
23
24 cancer cell migration in a TACS-3 setting. In previous work from our laboratory, we
25
26 compared 3 different breast cancer cell lines (MDA-MB-231, MCF-7 and MDA-MB-468) for
27
28 their migratory behaviour in empty collagen scaffolds [3]. We found that MDA-MB-231 cells
29
30 were the most invasive. Thus, to provide us with sufficient migratory cells to compare
31
32 scaffolds with and without the adipocyte fat pad, we chose this cell line and labelled them
33
34 with the fluorescent protein tdTomato using lentiviral methods (Supplementary Fig. 1) to
35
36 distinguish them from the E6/E7-hMSC. Anisotropic scaffolds invested with differentiated
37
38 E6/E7-hMSC (human adipose model), alongside empty scaffold controls, were then seeded
39
40 with tdTomato⁺ MDA-MB-231 cells into their scaffold funnels, cultured for 7 days and
41
42 imaged using 2-photon microscopy (Fig. 5a) This methodology was according to a modified
43
44 version of our previously published migration assay [3].
45
46
47
48
49

50
51 2pf and SHG revealed that after 7 days culture, the majority of tdTomato⁺ MDA-MB-231
52
53 cells in empty scaffolds were located within close proximity to the seeding funnel located at
54
55 the top of the scaffold and also on the outer surface (Fig. 5b, red). In contrast, when co-
56
57
58
59
60

1
2
3 cultured with differentiated E6/E7-hMSC, tdTomato⁺ MDA-MB-231 cells were observed at
4 all depths of the scaffold and were not confined to the funnel region (Fig. 5c). This
5 demonstrated that MDA-MB-231 cells can survive in this environment and that adipocytes
6 enhanced their migratory potential.
7
8
9
10

11 Discussion

12
13 In order to develop a 3D culture model of utility for analysis of breast tumour cell
14 invasiveness and response to therapeutic drugs, we generated an immortal hMSC line from a
15 breast reduction mammoplasty and demonstrated that these cells can be induced to
16 differentiate into adipocytes in an anisotropic collagen scaffold. Furthermore, we have
17 analysed the influence of the adipocyte microenvironment on the invasiveness of breast
18 cancer cells.

22
23
24
25
26
27
28
29
30

31 It is interesting that the E6/E7 genes were more successful in immortalising hMSCs than
32 hTERT. It is not clear why this should be, however, one possible explanation is that E6 and
33 E7 interact with the master regulators of the cell cycle, p53 and pRB, respectively increasing
34 the likelihood of immortalisation [29–31]. In contrast, although hTERT has been used
35 successfully to immortalise a range of cell types, it was unable in our system to prevent
36 telomere-controlled senescence [32].
37
38
39
40
41
42
43
44
45

46 The immortalised E6/E7-hMSC cell line is capable of *de novo* synthesis of lipids and extra-
47 cellular matrix (ECM) proteins, such as laminin and collagen IV, in both 2D and within 3D
48 anisotropic collagen scaffolds. Thus, our model comprises anisotropic collagen I, laminin,
49 collagen IV and mature adipocytes; all major components of the stroma surrounding breast
50 tumours with a poor prognosis [1,2].

54
55
56
57
58
59
60

1
2
3
4
5 Refractive index matching using reagents such as CUBIC, in conjunction with
6 immunostaining and multiphoton imaging, allows direct imaging of collagen with SHG with
7 the added advantage that the structural integrity of the tissue is relatively uncompromised.
8 Hence, these techniques facilitated the detailed 3D visualisation of tumour cells associated
9 with anisotropic collagen fibres.
10
11
12
13
14
15
16
17

18 Following 2D adipogenesis, E6/E7-hMSC synthesised the basement membrane proteins
19 laminin and collagen IV, as previously reported in hMSCs and the murine preadipocyte 3T3-
20 L1 cell line [25–28]. Although 2D adipogenesis was successful, it could not be presumed that
21 scaffold culture would produce similar results since hMSC differentiation potential is
22 affected by factors such as 3D culture, ECM substrate and surface topography [33–35].
23 Therefore, E6/E7-hMSC were differentiated within anisotropic collagen scaffolds to generate
24 a human adipose model. Synthesis of lipids, laminin and collagen IV were all indicative of
25 successful differentiation of E6/E7-hMSC to adipocytes and provide evidence that our model
26 can recapitulate certain aspects of the breast stroma. It is worth noting that migration of
27 MDA-MB-231 cells can be enhanced by uptake of lipid-derived fatty acids [8,36].

40
41

42 In conclusion, we have demonstrated the seeding and tracking of human breast cancer cells,
43 from the aggressive MDA-MB-231 cell line, in a physiologically relevant 3D *in vitro* tissue
44 engineered adipose model. This system successfully recapitulates multiple stromal elements
45 of the breast tumour microenvironment and provides scientists with a novel tool to
46 investigate cancer cell migration. Furthermore, these findings warrant further development to
47 analyse additional breast cancer cell lines and to include breast cancer patient tumour

Supplementary Table 1

Antibiotic	Concentration (µg/ml)	Dead MSC after 5 days (approx.)
Geneticin (G418)	0	1%
	150	75%
	300	90%
	400	98%
	500	99%
	600	100%
Puromycin	0	1%
	0.05	10%
	0.1	30%
	0.2	50%
	0.5	95%
	1	100%

Supplementary Table 1 - Kill curve to determine minimum antibiotic concentration required for the selection of immortalised hMSCs.

Non-transfected hMSC were treated with increasing concentrations of Geneticin/G418 and Puromycin. After 5 days treatment, cell death was quantified by the percentage of non-attached cells observed using light microscopy.

Supplementary Table 2

Plasmid name	Immortalising Gene	Antibiotic resistance	Concentration for selection
pLXSN-neo-E6E7	E6E7	Neomycin / G418 /Genetecin	600 µg/ml
pBABE-puro-hTERT	hTERT	Puromycin	1 µg/ml

Supplementary Table 2 - Optimal antibiotic concentrations for the selection of immortalised hMSCs.

The plasmids used for retroviral insertion of the E6E7 and hTERT genes for immortalisation and the corresponding antibiotic concentrations used for selection in hMSCs.

Figure legends

Figure 1 - The TACS-3 signature analysed in a human breast tumour biopsy using histological, optical clearing and 2-photon microscopy techniques.

A fresh human oestrogen receptor positive (ER⁺) / human epidermal growth factor receptor negative (HER2⁻) invasive ductal carcinoma (IDC) grade 2 was fixed following surgery and processed for either histological or CUBIC optical clearing. Grade, ER and HER2 status were determined by a trained medical pathologist (QMUL, Bart's Institute, UK). **a)** Paraffin embedded sections were stained with Masson's Trichrome; collagen (blue), nuclei (dark purple), cytoplasm (red). Columns of tumour cells can be seen invading between adipocytes (*) of the surrounding fat pad via anisotropic collagen fibres (arrows). Structures identified were confirmed by Dr. Raza Ali (University of Cambridge, CRUK), a trained medical pathologist. **b)** CUBIC optically cleared tumour fragment imaged using stereoscopic microscopy. **c)** Tumour fragment from b, imaged using two-photon fluorescence microscopy (2pf) and second harmonic generation (SHG) to visualise DAPI (round, white) and collagen (long fibrous, white), respectively. Directional anisotropic collagen fibres can be observed running right to left. A confocal z-stack is represented as individual z-slices. **d)** Tumour fragment and same z-sections from c, whole mount immunostained for keratin-8 (green) and ER (red) and imaged using 2pf. DAPI (blue) and collagen (blue) imaged with 2pf and SHG, respectively. Keratin-8⁺ ER⁺ epithelial cells can be observed, often in single file procession directionally aligned with anisotropic collagen fibres.

Figure 2 – Human mesenchymal stem cells (hMSCs) immortalised by insertion of E6/E7 genes escape senescence, have increased proliferative capacity and maintain successful adipogenic differentiation.

Human telomerase reverse transcriptase (hTERT) or E6/E7 genes were retrovirally inserted into hMSCs. These cell lines were named hMSC (non-transfected control), hTERT-hMSC and E6/E7-hMSC. **a)** Senescent cells were marked using β -galactosidase and produced a green stain (arrowheads). Due to low sensitivity of the assay, colour saturation and contrast alterations were applied equally all images (second row) to highlight differences between cell lines. Cells were at passage 12. **b)** Immunocytochemistry for proliferation marker Ki67 (green) on undifferentiated cell lines or after 11 days adipogenic induction. Nuclei marked with Hoechst (blue). **c)** The ratio of Ki67⁺ nuclei to all cell nuclei was plotted for each cell line. Statistical significances were determined using an unpaired one-way ANOVA test (n=3, different passages). **p<0.01, ***p<0.001. **d)** Oil red O histological staining for intracellular lipids (red) to mark adipogenic differentiation. **e)** Western blotting of cell extracts, for the lipid vesicle marker perilipin (62 kDa) to mark differentiation. 'Adipo' samples are following 11 days adipogenic induction. GAPDH (37 kDa) and HEK293T cells were used as loading and negative controls, respectively.

Figure 3 – E6/E7-hMSC synthesise basement membrane proteins upon adipogenesis.

Immunocytochemistry of hMSC (non-transfected control), hTERT-hMSC and E6/E7-hMSC that are either undifferentiated or after 11 days adipogenic induction for basement membrane proteins **a)** laminin (green) and **b)** collagen IV (green). Nuclei were marked with Hoechst dye (blue). Image J analysis of detectable fluorescence for **c)** laminin and **d)** collagen IV. A.U. stands for arbitrary units. One way ANOVA statistical test was used to compare samples (n=3, different passages). *p<0.05, **p<0.01, ****p<0.0001.

4 **Figure 4 - E6/E7-hMSC successfully undergo adipogenesis and synthesise basement**
5 **membrane proteins in anisotropic collagen scaffolds to produce the human adipose**
6 **model.**

7 **a)** Following immortalisation of hMSC by retroviral insertion of E6 and E7 genes and
8 antibiotic selection, E6/E7-hMSC were seeded in anisotropic collagen scaffolds, cultured for
9 7 days for proliferation and differentiated for 11 days with an adipogenic cocktail to
10 produce the human adipose model. Scaffolds were then fixed, whole mount immunostained
11 and imaged using 3D microscopy techniques. **b)** Immunostaining for the lipid vesicle and
12 adipogenic marker perilipin (green). DNA marked with DAPI (blue). Tiled image z-stacks of
13 undifferentiated E6/E7-hMSC and E6/E7-hMSC following adipogenesis, with zoomed in
14 images (i,ii) and a digitally magnified image (ii, box insert). **c)** Scaffolds following
15 adipogenesis from b, were imaged using non-linear excitation coherent anti-raman
16 spectroscopy (CARS) to visualise lipids (red) directly. Perilipin (green) and DAPI (white) were
17 imaged using 2-photon fluorescence excitation. Collagen was imaged directly using SHG
18 microscopy (white). Image is shown as a maximum intensity projection of a z-stack. **d,e)**
19 Immunostaining for basement membrane proteins laminin (d, green) and collagen IV (e,
20 green). DNA is marked with DAPI (blue). Confocal images are shown as maximum intensity
21 projections of DAPI, laminin/collagen IV and merged (white asterisk), or as a z-depth colour
22 coded image of the laminin/collagen IV channel (white asterisk).

30 MDA-MB-231 cells were lentivirally transduced to express the tdTomato fluorescent
31 protein. **a)** FACS sorting of tdTomato MDA-MB-231 cells based on tdTomato fluorescence.
32 **b)** Immunofluorescence of tdTomato MDA-MB-231 cells based on tdTomato fluorescence
33 (red). DNA marked using Hoechst dye (blue). **a,b)** Non-transfected MDA-MB-231 cells were
34 used as a negative control.
35
36

37 **Figure 5 – The human adipose model promotes the migration of the MDA-MB-231 breast**
38 **cancer cell line.**

39 **a)** Empty anisotropic collagen I scaffolds and the human adipose model, were seeded with
40 tdTomato-expressing MDA-MB-231 cells into the scaffold funnels and cultured for 7 days.
41 Scaffolds were then fixed, bisected and DNA was marked. Scaffolds were then imaged using
42 2-photon microscopy. **b)** Empty scaffold control and **c)** human adipose model 2-photon
43 microscopy images are shown. Collagen was imaged directly using SHG (blue). SYTO16
44 (green) was used to mark DNA and was imaged using 2pf. tdTomato-expressing MDA-MB-
45 231 cells were imaged using 2pf.

Figure 1

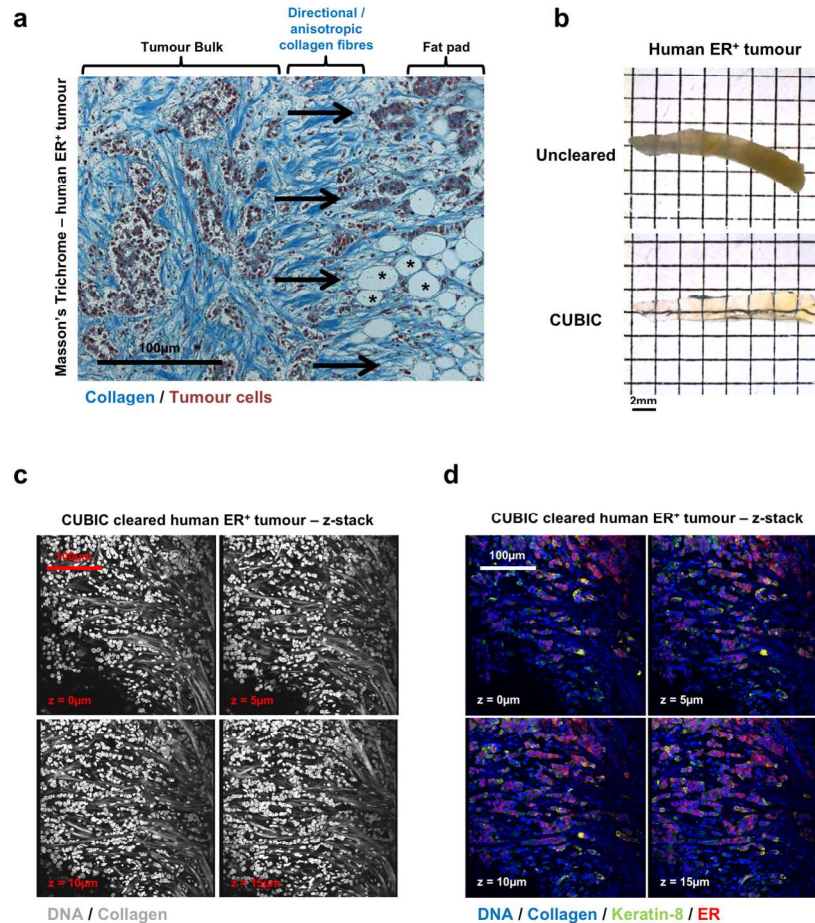

Figure 1 - The TACS-3 signature analysed in a human breast tumour biopsy using histological, optical clearing and 2-photon microscopy techniques.

A fresh human oestrogen receptor positive (ER⁺) / human epidermal growth factor receptor negative (HER2⁻) invasive ductal carcinoma (IDC) grade 2 was fixed following surgery and processed for either histological or CUBIC optical clearing. Grade, ER and HER2 status were determined by a trained medical pathologist (QMUL, Bart's Institute, UK). a) Paraffin embedded sections were stained with Masson's Trichrome; collagen (blue), nuclei (dark purple), cytoplasm (red). Columns of tumour cells can be seen invading between adipocytes (*) of the surrounding fat pad via anisotropic collagen fibres (arrows). Structures identified were confirmed by Dr. Raza Ali (University of Cambridge, CRUK), a trained medical pathologist. b) CUBIC optically cleared tumour fragment imaged using stereoscopic microscopy. c) Tumour fragment from b, imaged using two-photon fluorescence microscopy (2pf) and second harmonic generation (SHG) to visualise DAPI (round, white) and collagen (long fibrous, white), respectively. Directional anisotropic collagen fibres can be observed running right to left. A confocal z-stack is represented as

1
2
3 individual z-slices. d) Tumour fragment and same z-sections from c, whole mount immunostained for
4 keratin-8 (green) and ER (red) and imaged using 2pf. DAPI (blue) and collagen (blue) imaged with 2pf and
5 SHG, respectively. Keratin-8+ ER+ epithelial cells can be observed, often in single file procession
6 directionally aligned with anisotropic collagen fibres.
