A p-type heterojunction photoelectrode consisting of platinized CuBi$_2$O$_4$ layered on a CuO film was prepared. The CuO/CuBi$_2$O$_4$/Pt electrode photo-generates H$_2$ in pH neutral aqueous solution during visible light irradiation and exhibits a substantially enhanced photocurrent compared to CuO/Pt and CuBi$_2$O$_4$/Pt electrodes. Reduced electron-hole recombination by the band offsets in the heterostructure is responsible for the improved photoelectrochemical performance of CuO/CuBi$_2$O$_4$ with a small band-gap of approximately 1.5 eV.

The development of an efficient, stable, and scalable photocatalyst for the conversion of solar energy into chemical energy is a major goal to address the energy challenge of this century. Photolysis of water into H$_2$ and O$_2$ on semiconductors has been studied for decades, and current efforts focus on the discovery of small band-gap photocatalysts with high activity during visible light irradiation.

Theoretically, a band-gap of less than 1.8 eV would allow for a photon-to-H$_2$ conversion efficiency of more than 20%.

A common strategy to achieve high efficiency is pairing a small band-gap photocathode for H$_2$ production with a semiconductor photoanode with complementary light absorption for water oxidation. Beyond efficiency, the semiconductor electrodes must also be made of inexpensive materials, easy to fabricate and display long-term stability in aqueous electrolyte solution.

Despite a large number of encouraging n-type photoanodes being available, there are only a few promising candidates for efficient p-type photocathodes for the H$_2$ evolution reaction (HER). Many p-type semiconductors, e.g., p-doped Si, Cu$_2$O, InP, Cu$_2$ZnSnS$_4$, CuIn$_2$Ga$_3$Se$_8$, WSe$_2$, CuRhO$_2$, CuO, and CuBi$_2$O$_4$, have been discussed for the photoelectrochemical (PEC) HER using solar energy. However, these photocathodes have currently restricted utility due to their high cost and/or rapid photo-decomposition in aqueous solution.

CuBi$_2$O$_4$ is a natural mineral semiconductor with a tetragonal structure, which is (photo)-chemically unstable in acidic and pH neutral aqueous solution. Despite the attractive band-gap size of approximately 1.5 to 1.8 eV of the p-type semiconductor, there is only a limited number of studies where CuBi$_2$O$_4$ was employed as a photocatalyst. CuO is another attractive and promising p-type semiconductor with a small band-gap. It has a conduction band position suitable for HER and has been used as coating on TiO$_2$ and CuO for visible light absorption and to improve the photochemical stability of the electrode, respectively. However, CuO and CuBi$_2$O$_4$ suffer from severe photo-degradation in aqueous solution through photo-reduction to metallic copper.

Herein, we report on the facile preparation of an inexpensive photocathode based on a CuO/CuBi$_2$O$_4$ heterojunction coated with Pt for visible light promoted HER in pH neutral aqueous electrolyte solution (Figure 1). The enhanced photocurrent is the result of improved electron-hole separation by utilizing the valence band offsets at the heterojunction interface and the Pt-layer enhanced the photostability of the CuO/CuBi$_2$O$_4$ heterojunction.
approximately 100 nm for the FTO/CuO and FTO/CuO/CuBi₂O₄ heterojunction films, whereas a smooth surface was observed for the FTO/CuBi₂O₄ film (Figure 1 and S2). The FTO/CuO/CuBi₂O₄ heterojunction film shows a porous structure similar to that of FTO/CuO with a film thickness of about 300 nm as shown in the cross section image in Figure S2.

The photocactivity of the Pt-free electrodes was first studied by linear sweep voltammetry (LSV) and chronoamperometry (CA) at 0.2 V vs. normal hydrogen electrode (NHE) in a pH 6.8 aqueous solution (Figure S3 and S4). An AM 1.5G solar light irradiator with a UV-vis light intensity of 100 mW cm⁻² was employed. As expected, FTO/CuO, FTO/CuBi₂O₄, and FTO/CuO/CuBi₂O₄ showed poor photo-stability due to the photocorrosion of CuO during irradiation. (Figure S4). The photocurrent onset at FTO/CuBi₂O₄ in LSV runs was observed at approximately 100 mV more positive potential compared to FTO/CuO (Figure S3). The positive onset potential of the FTO/CuBi₂O₄ electrode indicates a more positive flat-band or valence band edge potential of FTO/CuBi₂O₄ in agreement with previous reports in the literature.²⁻³ Mott-Schottky plot analysis resulted in a flat-band potential of CuO and CuBi₂O₄ of 0.69±0.01 V and 0.81±0.03 V vs. NHE in neutral aqueous electrolyte solution (Figure S5), respectively, which is in agreement with the onset potentials in the LSV measurements.

PEC experiments with the FTO/CuO, FTO/CuBi₂O₄ and FTO/CuO/CuBi₂O₄ heterojunction electrodes in acetonitrile solution in the presence of an electron acceptor, ethyl viologen diperoxochlorate (EV⁻⁴) were subsequently performed to avoid photodegradation in water with the bare metal oxide electrodes (Figures S6 and S7).³⁻⁴,²⁰,²³ The photocurrent measured under these conditions did not contain any background current from electrode photocorrosion and was therefore smaller than in the aqueous solution. Consequently, the FTO/CuO and FTO/CuBi₂O₄ electrodes show stable photocurrent without noticeable photodegradation in acetonitrile solution (Figure S7). The steady-state photocurrent measured by CA was only approximately 30% of the transient photocurrent for all electrodes measured by LSV and the large transient behavior, including peak-shaped photocurrent response in the LSV, indicates significant surface recombination at the photocathodes and visible light absorption by EV⁺ formed at the electrode surface.³ Investigation of systematic surface passivation would be an efficient method to further reduce the recombination rate at surface defects and leading to an enhanced photocurrent.

The effect of different amounts of the Cu-based semiconductors deposited on FTO on the photocurrent was also studied in acetonitrile with EV⁻⁴ for each electrode (Figure S7). The optimized amount of metal ions was 2.2, 0.45, and 2.20±0.45 μmol cm⁻² for CuO, CuBi₂O₄, and CuO/CuBi₂O₄, respectively, used for electrode preparations in further experiments (cross-section images and film thickness are shown in Figure S2). Thicker films resulted in a decreased photocurrent response or physical instability.

The CuO/CuBi₂O₄ heterojunction displayed a substantially higher photocurrent in LSV and CA measurements than the homo-layered FTO/CuO or FTO/CuBi₂O₄ electrodes (Figure 2, S6, S7, and S8). For example, a three times higher photocurrent was obtained with the CuO/CuBi₂O₄ heterojunction for EV⁻⁴ reduction than with the homo-layered electrodes at -0.45 V vs. NHE (Figure S7).

The higher photocurrent results from better electron-hole separation in the CuO/CuBi₂O₄ heterojunction than in CuO or CuBi₂O₄ for the following reasons: the photocurrent at FTO/CuO or FTO/CuBi₂O₄ was not limited by light absorption (thickness dependence in Figure S7D) and not hindered by the reaction kinetics for EV⁻⁴ reduction.³⁶ The gradual increase of photocurrent observed at the CuO/CuBi₂O₄ heterojunction during CA can be assigned to structural changes at the CuO and CuBi₂O₄ interface (Figure S7C and S9).³²

The Pt electrocatalyst was then photo-deposited on the electrodes from an aqueous K₂PtCl₄ solution (see ESI and Figure S10) in order to enhance the activity and stability of the photocathodes in aqueous electrolyte solution during illumination.³³⁻³⁵

Photocurrents with FTO/CuO/CuBi₂O₄ Pt and FTO/CuO/CuBi₂O₄ Pt electrodes were more than twice as high as at FTO/CuO/Pt and FTO/CuBi₂O₄/Pt. In addition, the Pt-modified electrodes exhibited a small improvement in photostability compared to the Pt-free electrodes and reduced photodegradation was observed after 10 min irradiation in the aqueous solution (Figure 2 and S11). A steady-state photocurrent of 100 and 80 μA cm⁻² was observed during CA for the FTO/CuO/CuBi₂O₄ electrode under UV-vis and visible light (λ > 420 nm) irradiation, respectively. Thus, approximately 80% of the photocurrent is generated by λ > 420 nm light absorption at the heterojunction electrode (Figure 3). However, photocurrents with FTO/CuO/CuBi₂O₄/Pt do not still display long term stability and currents started to decrease quickly after approximately 10 min, with approximately 60% of the photocurrent remaining after 20 min (Figure S11D). The photo-instability of FTO/CuO/CuBi₂O₄ Pt originates presumably from non-conformal coating of the electrocatalyst on the photocathode and the resulting lack of complete protection from the electrolyte solution (Figure S10).³⁻⁵ LSV scans also indicate a non-negligible dark current with FTO/CuO/CuBi₂O₄/Pt and FTO/CuO/Pt electrodes (Figure 2A), which indicates possible reduction of the photocathodes. Studies to ensure longer time stability of photocathodes with conformal and noble-metal free coatings in aqueous solution are currently in progress in our laboratory.

Mott-Schottky plots of FTO/CuO and FTO/CuBi₂O₄ allowed us to determine the flat-band potentials of the heterojunction, which is closely placed to the valence band edge for a heavily p-doped semiconductor such as CuO and CuBi₂O₄. The size of the band gap, or position of conduction band-edge of CuO and CuBi₂O₄ could not be unambiguously determined by UV-vis absorption spectroscopy and Tauc plots (Figure S12) and is not precisely known from the literature.²²⁻²⁴,³⁸ CuO was reported with a wide range of indirect band gap of 1.2 to 1.9 eV²⁸,³⁸ and CuBi₂O₄ with a band gap between 1.5 to 1.8 eV.²³,³⁸ We expect the band-gap size to be larger than 1.2 eV for CuO and greater than 1.3 eV for CuBi₂O₄ based on the observed photoreduction of EV⁻⁴ and proton reduction reactions both at the FTO/CuO and FTO/CuBi₂O₄ electrodes as shown in Figure 2 and S6.
The valence band offsets or internal electric field given in the heterojunction indicates that enhanced electron-hole separation can occur in the heterostructured electrode of CuO and CuBi2O4. The heterojunction of FTO/CuO/CuBi2O4/Pt generates at least twice the photocurrent of homo-layered FTO/CuO/Pt or FTO/CuBi2O4/Pt electrodes due to the reduction of electron-hole recombination by the band offsets provided in the heterostructure. In contrast, a deteriorating effect was observed with an inverted heterojunction, i.e., FTO/CuBi2O4/CuO. With this electrode, a reduced photocurrent results from the deep valence band of CuBi2O4 and the resulting trapping of holes and increased electron-hole recombination at the interfaces between the CuBi2O4 and CuO layers (Figure S13).

H2 generation at the photocathodes was confirmed by electrochemical detection of H2 (Figure S14): a Pt ultramicroelectrode (UME) with a diameter of 100 μm with an applied potential of −0.3 V for H2 oxidation was placed near (at an estimated distance of approximately 500 μm) the FTO/CuO/CuBi2O4/Pt electrode to detect H2 during back-side irradiation of the photocathode (see Experimental Section in ESI for details). Thereby, H2 diffuses from the photodecay to the Pt UME and the H2 oxidation current at the latter is proportional to the H2 evolved at the former electrode. Note that the FTO/CuO/CuBi2O4/Pt electrode has a small electrode area and was largely covered by an insulating epoxy resin resulting in a small current in Figure S14. A H2 oxidation current was observed at the Pt UME upon irradiation of the FTO/CuO/CuBi2O4/Pt electrode. The oxidoxidation current at Pt demonstrates H2 evolution at the photocathode.

The photocatalyst Pt on the heterojunction facilitates the reaction kinetics for HER and fewer photoexcited electrons are consumed for the electrode decomposition reactions shown in Eqs. 1 and 2.1,2,15 We note that H2 was only detected at the Pt UME with the FTO/CuO/CuBi2O4/Pt photocathode, but not at FTO/CuO/CuBi2O4 without Pt, where the photocurrents are mainly due to photodecomposition of the heterojunction electrode.15,32,38,40 Previously, photodecomposition of photocatalyst layers, e.g. Ru and Pt onto p-WSe2 for HER15 or Co-Pt on Ba-doped Ta:NiO for OER31, were used to fabricate the protective layers to reduce the photodecomposition reactions and to utilize electrons and holes primarily for HER and OER.

\[
2\text{CuO} + 2\text{H}_2\text{O} + 2e^- \rightarrow 2\text{Cu}^{2+} + 4\text{OH}^- \quad (E^0 = 0.20 \text{V vs. NHE}) \quad (1)
\]

\[
\text{Cu}_2\text{O} + \text{H}_2\text{O} + 2e^- \rightarrow 2\text{Cu} + 2\text{OH}^- \quad (E^0 = 0.07 \text{V vs. NHE}) \quad (2)
\]

Incident photon to current conversion efficiencies (IPCE) of FTO/CuO/CuBi2O4/Pt with UV-vis absorption spectra shown in Figure 3 indicate an excellent visible light response of the heterojunction electrode (see ESI for details). The heterojunction electrode shows maximum IPCE of 60% at 0 V for high-energy photon absorption, and shows a visible response at the wavelength up to 850 nm. The effective band-gap size of FTO/CuO/CuBi2O4/Pt electrode is therefore approximately 1.5 eV based on IPCE measurements. In addition, integration of the photocurrent over the wavelength from the IPCE measurements in Figure 3A further confirmed the efficient visible light harvesting of the heterojunction electrode (Figure 3B). Figure 3B shows the wavelength dependent photocurrent produced by absorbed photons. More than 80% of the photocurrent was generated by visible light irradiation with wavelength longer than 420 nm. The visible light response of the heterojunction in LSVs is also shown in Figure S15. IPCE values at various applied potentials in Figure S16 show that the photoactivity enhancement in the heterojunction electrode appeared under monochromatic irradiation agrees well with the visible light response in Figure 2. Note that the beam intensities used for IPCE measurements indicated in Figure 3A were different from the AM 1.5 irradiance, which can affect IPCE values.31

In summary, a CuO/CuBi2O4/Pt electrode for visible light driven H2 evolution in aqueous electrolyte solution is reported. The novel heterojunction electrode structure reduces charge recombination, has a narrow band-gap of approximately 1.5 eV and can be stabilized in water with a suitable electrocatalyst layer. CuO/CuBi2O4 is also easy to assemble, does not contain prohibitively expensive materials and is therefore a promising candidate for visible absorption and charge-separation in solar-to-fuel conversion devices with theoretical efficiencies of more than 20%.2,3 CuO and CuBi2O4 form an excellent heterojunction pair, which more than doubles the photoactivity compared to the corresponding monolayer electrodes. Work to further increase the performance and stability of photoelectrodes in aqueous solution and replacement of Pt by inexpensive electrocatalysts is currently in progress in our laboratory.
