Natural Products

Total Syntheses of Linear Polythiazole/Oxazole Plantazolicin A and Its Biosynthetic Precursor Plantazolicin B**

Zoe E. Wilson, Sabine Fenner, and Steven V. Ley*

Abstract: Plantazolicin A, a linear decacyclic natural product, exhibits desirable selective activity against the causative agent of anthrax toxicity. The total synthesis of plantazolicin A and its biosynthetic precursor plantazolicin B was successfully achieved by an efficient, unified, and highly convergent route featuring dicyclizations to form 2,4-concatenated oxazoles and the mild synthesis of thiazoles from natural amino acids. This report represents the first synthesis of plantazolicin B and includes the first complete characterization data for both natural products.

Plantazolicin A (1a) and its biosynthetic precursor plantazolicin B (1b) represent a new class of ribosomally synthesized thiazole/oxazole natural products isolated from the soil bacterium Bacillus amyloliquefaciens FZB42 (Scheme 1).\[1,2\]

The biosynthesis of these molecules has been shown to involve the extensive post-translational modification of a 14-amino-acid peptide to give 1b, which has two pentaheterocyclic regions, one of which is not fully oxidized in an unusual overall linear structure. Plantazolicin B (1b) undergoes dimethylation at the N-terminus to afford 1a.\[3\] Subsequent investigations by Mitchell et al. have shown that the absolute stereochemistry of 1a is derived from all natural L-amino acids.\[4\]

Plantazolicin A (1a) has been reported to exhibit antibacterial activity against related gram-positive bacteria, including, notably, the causative agent of anthrax toxicity, Bacillus anthracis (strain STERN), whereas 1b is inactive.\[5\] The challenging linear structures of these molecules, in combination with the desirable biological activity of 1a, makes them attractive targets for total synthesis. Süßmuth and co-workers have recently reported the synthesis of 1a\[6\] and Mitchell et al. have reported the preparation of shortened analogues of the left-hand half, as drawn, of 1a.\[7,8\] However, the total synthesis of the demethyl precursor 1b has not been reported to date. The primary goal of our research was to develop a unified, efficient, and convergent strategy for both 1a and 1b, which we report herein.

Our strategy was based upon a late-stage peptide coupling of two equally sized fragments, 3 and either 2a or 2b (Scheme 1). Our quest to obtain the left-hand fragment of both 1a and 1b was designed based on the union of three components: the tripeptide 9 and two thiazole-containing fragments, that is, 5 and either 4a or 4b. The planned installation of arginine-derived thiazole 4a or 4b as the penultimate step of these fragments would allow a highly unified approach to the synthesis of both natural products. Initial attempts at employing a modified Hantzsch thiazole synthesis\[9\] for 4a and 4b were low yielding and unreliable, echoing the recently published works on similar fragments by the groups of Süßmuth and Mitchell, where the preparation of the required thiocarbonate precursors in particular were low yielding (13%\[9\] and 25\%\[10\] respectively) and required the use of unpleasant sulfurating reagents. Therefore it was decided to attempt a more biomimetic approach to these thiazoles, based on the condensation of an amino-acid-derived aldehyde with a cysteine ester hydrochloride, followed by oxidation of the resultant thiazolidine.\[7\] It was hoped that the use of 9 as a coupling partner would allow the formation of the two adjacent 5-methyl oxazole rings in a single step by using a modification of Wipf's conditions for the cyclization of β-hydroxy amides.\[9\]

The synthesis of the right-hand fragment 3 was based on the union of the tetraoxazole 6 and dipeptide 7. It was thought that a double cyclization/oxidation, this time of serine residues, could also be employed during the construction of 6\[8\] after two successive coupling then cyclization/oxidation of serine residues to form the dioxazole 10. Overall, it was proposed that both fragments could be obtained from inexpensive natural L-amino acid starting materials, which correspond directly to those used in the biosynthesis of these natural products. The only exception to this would be the use of the L-allo-threonine 21 to allow a Decoxo-Fluor-mediated oxazolidine formation, as this proceeds with inversion of the configuration at the β-position of the amino acid.\[11,12\]

The assembly of left-hand fragments 2a and 2b commenced with the straightforward preparation of 9 through two successive couplings using 1-hydroxybenzotriazole hydrate (HOBt) and N-(3-dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDCI) with diisopropylethylamine as a base in dichloromethane in an overall yield of 78% (Scheme 2).

Next, attention turned to the formation of known thiazole 8 (Scheme 3). Threonine-derived Weinreb amide 24 was readily synthesized from the Boc-threonine 14 before reduction using diisobutylaluminium hydride (DIBAL-H), which gave the amino aldehyde which was immediately condensed with the

cysteine ethyl ester hydrochloride salt \textsuperscript{15}, before oxidation of thiazolidine \textsuperscript{25} using manganese dioxide to give \textsuperscript{8} in an overall yield of \(42\%\). This yield was comparable to those obtained previously for \textsuperscript{8}, but avoided the use of sulfurating reagents.\textsuperscript{[13]} No epimerization of either chiral center was observed.

This approach was then applied to the assembly of the challenging arginine-derived thiazoles \textsuperscript{4a} and \textsuperscript{4b} (Scheme 4). Significant optimization determined that both \textsuperscript{4a} and \textsuperscript{4b} could be accessed by a common route. Commercially available tri-Boc-arginine \textsuperscript{12} could be readily converted into the Weinreb amide \textsuperscript{26} before reduction, condensation with cysteine methyl ester hydrochloride \textsuperscript{13}, and MnO\textsubscript{2}-mediated oxidation to afford \textsuperscript{4b} in an acceptable \(41\%\) overall yield. This approach is a marked improvement on the previous synthesis for related fragments. Removal of all nitrogen protecting groups from \textsuperscript{4b} allowed the selective dimethylation of the \(\alpha\)-nitrogen atom by reductive amination using aqueous formaldehyde and sodium cyanoborohydride.\textsuperscript{[12]} Reprotection of the guanidine moiety afforded \textsuperscript{4a} in \(35\%\) yield (3 steps) and minor amounts (\(13\%\)) of regioisomer \textsuperscript{28} which could feasibly be progressed further if desired.

Completion of the left-hand fragment then continued with assembly of the three building blocks. Deprotection of tripeptide \textsuperscript{9} and ester hydrolysis of \textsuperscript{8} followed by peptide coupling led to cyclization precursor \textsuperscript{29} in good yield (Scheme 5). It was then found that a one-pot, double cyclization/oxidation could be effected using a modification of Wipf’s conditions\textsuperscript{[6]} to give 2,4-concatenated triazole \textsuperscript{5} in an excellent yield of \(64\%\). To our best knowledge this is the first example of such a transformation, and represents a useful extension of Wipf’s methodology.

The synthesis of the pentacycles \textsuperscript{2a} and \textsuperscript{2b} was then completed by deprotection of the N-terminal threonine residue of \textsuperscript{5} using hydrochloric acid in 1,4-dioxane/water to afford the hydrochloride salt, which was coupled directly with the acids resulting from the careful hydrolysis of the esters of \textsuperscript{4a} and \textsuperscript{4b}, using 1-[bis(dimethylamino)methylene]-1H-1,2,3-triazolo[4,5-b]pyridinium 3-oxid hexafluorophosphate (HATU) in the presence of disopropylethylamine (Scheme 6). One-pot cyclization/oxidation of \textsuperscript{30a} and \textsuperscript{30b} with Deoxo-Fluor then Br\textsubscript{CCl\textsubscript{3}} and DBU afforded \textsuperscript{2a} and \textsuperscript{2b}, respectively in good yield.

The synthesis of the common right-hand fragment \textsuperscript{3} commenced with the preparation of the dipeptide \textsuperscript{31} followed by one-pot cyclization/oxidation to reliably provide oxazole \textsuperscript{32} on a multigram scale (Scheme 7). This process was then repeated to give methyl ester \textsuperscript{10} in \(78\%\) yield. After saponification, \textsuperscript{10} was coupled to the deprotected serine dipeptide \textsuperscript{11} to give \textsuperscript{33}. A step-efficient double cyclization/
oxidation could then be performed to provide tetraoxazole 6 in an excellent yield of 77%.

Boc-protected *allo*-threonine[14] 35 was coupled to the trimethylsilyl ethyl (TMSE) protected phenylalanine 36 using HATU and diisopropylethylamine (Scheme 8). The resulting dipeptide, 7, and 6 were deprotected under previously employed conditions, taking care to avoid epimerization of the *allo*-threonine during the deprotection, and coupled in 77% yield to successfully complete the construction of the right-hand fragment 3.

With a successful route to the coupling partners for both 1a and 1b accomplished, all that remained was the deprotection of the final coupling partners and coupling using HATU in the presence of disopropylethylamine (Scheme 9). After partial purification the *allo*-threonine residues of coupled products 37a and 37b were cyclized using Deoxo-Fluor to give the oxazoline-containing protected natural products 38a (43%) and 38b (35%), respectively. Pleasingly, it was then found that removal of both the Boc and TMSE protecting groups could be effected in a single step by treatment with trifluoroacetic acid (TFA) to deliver both the natural product plantazolicin A 1a and its biosynthetic precursor plantazolicin B 1b after HPLC purification. The products were identical in all respects to published data (full characterization and comparison of synthetic and natural plantazolicin A is included in the Supporting Information of this paper). To our knowledge this is the first reported complete characterization of 1b.

In conclusion, we have developed an efficient, unified strategy for the total syntheses for both thiazole/oxazole natural product plantazolicin A (1a) and its biosynthetic precursor plantazolicin B (1b). This was achieved through
