Multiple Deprotonation of Primary Aromatic Diamines by LiAlH₄

Robert J. Less,*a Lucy K. Allen,a Alexander Steinerb and Dominic S. Wrighta

Reaction of LiAlH₄ with 1,2-phenylenediamine (1H₂) in THF results in formation of the metallocyclic amido-/imido complex [[Al(1H₂)]₂[Al(1H₂)]₂][Li(THF)]₄ (3), while in the presence of various Lewis base ligands, 1,8-diaminonaphthalene (2H₄) gives the amido- (‘ate’) complexes [Al(2H₂)]₂[Li(LL’)]⁺ [L = THF, L’ = PMDETA (N,N,N’,N,,N’-pentamethyldiethylenetriamine) (4); L = L’ = TMEDA (N,N,N’,N’-Tetramethylethylenediamine) (5)]. The latter complexes provide evidence of intermediates in the proposed reaction pathway for formation of the cyclic framework of the tetraanion [[Al(1H₂)]₂[Al(1H₂)]₂]⁴⁺ of 3.

Our current focus on this area stems jointly from long standing interests in the synthesis and structural chemistry of main group metal imido complexes and their phosphanediide (RP₂) counterparts and from a more recent realization that key reagents which we have employed in their synthesis can be used to effect stoichiometric and catalytic dehydrocoupling of a range of bonds. Pertinent to the current study, we have found that the reaction of the redox-active superbase mixture Sb(NMe₂)₃/BuLi with the 1,2-(PH₂)₂C₆H₄ results in the formation of the benzo-1,2,3-triphosphilide anion [C₆H₄P₃]⁻ via a process involving a stepwise oxidative coupling of the P-H bonds (Scheme 1a), in combination with the reduction of Sb₃⁺ to a Zintl compound. Remarkably, the same type of coupling occurs in the case of the reaction of the diamine analogue o-phenylene diamine, 1,2-(NH₂)₂C₆H₄, with the superbase mixture Sn(NMe₂)₃/BuLi at elevated temperature, which gives the benzo-1,2,3-triazolyl anion and Sn metal (Scheme 1b).

(a)

(b)

Scheme 1 Reactivity of 1,2-C₆H₄(EH₂); (E = N, P) with p-block metal bases and BuLi.

Such N-H/N-H coupling is extremely rare even in the case of transition metal-mediated reactions and may have broader scope in the synthesis of a range of nitrogen heterocycles.

---

1. Introduction

Group 13 amido (R₂N⁻) and imido (RN⁻) compounds are important classes of main group metal nitrogen compounds owing to their potential use in a number of synthetic and technologically-important applications, such as reagents for organic and inorganic transformations and single-source precursors for technologically important III/V semiconductor materials (e.g., AlN and GaN). More recent developments in lithium amido aluminate chemistry include derivatives based on TMP (2,2,6,6-tetramethylpiperidide) as reagents to effect the metatalation of aromatic compounds. Group 13 amido (R₂N⁻) and imido (RN⁻) compounds have been obtained using a broad range of synthetic routes.

One interesting class of these compounds are alkali metal primary-amido aluminium ‘ate’ complexes containing [Al(NHR)₃]⁻ anions, which can be employed as precursors for imido complexes via deprotonation of the Al-bonded RH₃ groups with strong organometallic bases such as "BuLi. This approach to imido aluminium compounds can, however, suffer from the drawback that the NH protons may not be reactive enough to effect deprotonation, with the result that the RH functionality of the precursor is retained and the "BuLi base molecules are simply incorporated into the resulting cage structure. Alternatively, separate studies by Roesky, Chivers and Nöth have shown that direct reactions of lithium and sodium aluminium hydride (MAH₄; M = Li or Na) with secondary (R₂NH) and mono-functional primary amines (RNH₂) can be employed to produce a range of amido- and mixed amido/imido lithium ‘ate’ compounds.
Most recently it was found that amides, like Al(NMe₂)_3, and hydrides, such as (‘BuO)AlH₂ and LiAlH₄, are effective precatalysts for N-H/B-H dehydrocoupling. With this background in mind, we focus in the current study on the reactions of the most readily available reagent of this class (LiAlH₄) with aromatic diamines, with a view to exploring whether this simple reagent might also be capable of N-H/N-H dehydrocoupling.

2. Results and Discussion

Following on from previous studies in this area, we selected 1,2-phenylenediamine (1H₄) and 1,8-diaminonaphthalene (2H₄) as substrates for the current investigations (Fig. 1). Although 1H₄ and 2H₄ and anions derived from their deprotonation have been used extensively as ligands for a large number of transition metal complexes, only three examples of Group 13 complexes containing the doubly-deprotonated [1H₂]⁻ ligand are known (i.e., deprotonated at each of the NH₂ groups, see Scheme 2). In addition, only one example of a main group metal complex containing the [2H₂]⁻ has been structurally characterized previously (i.e., again with deprotonation at each of the NH₂ groups, see Scheme 3).

![Fig. 1 Structures of the precursor diamines used in the current work 1H₄ and 2H₄.](image)

Addition of solid LiAlH₄ to solutions of the diamines 1H₄ or 2H₄ using various stoichiometries in THF results in rapid exothermic reactions with the visible evolution of H₂ gas and the formation of colourless to light yellow solutions. Particular care had to be taken to ensure the rigorous exclusion of air from these reactions as the solutions generated react instantaneously with traces of atmospheric oxygen to give blue, purple or brown solutions (depending on the degree of contamination). Initially, a 1:1 ratio of the diamines to LiAlH₄ was employed in trial reactions, with the intention of fully deprotonating both amine groups to give the tetraanions [1]⁻ and [2]⁻. Unfortunately, in both cases the products of these reactions could not be isolated despite numerous attempts at crystallization. However, using a reduced ratio of LiAlH₄ with 1H₄ (2 : 3, respectively) in THF allowed the isolation of highly air-sensitive colourless crystals of the new aluminium complex [(Al(1H₂)₂)₂[Al(1H₂)₂]₂][Li(THF)₂]₄ (3) in 48% yield, containing doubly and triply-deprotonated 1H₂⁻ and 1H₃⁻ anions (Scheme 2).

The room-temperature ¹H NMR spectrum of crystalline 3 in D₅-THF (ESI) shows two distinct sets of aromatic C-H resonances for the [1H₁]⁻ [δ 6.16 (s) and 6.08 (s)] and [1H₂]⁻ [δ 50.6-6.5 (br. mult.)] ligands in the correct 1:1 ratio. However, the NH protons of these anions are indistinguishable and only appear as a broad singlet (δ 3.08 ppm), but with the correct 24:8 ratio with respect to the total aromatic C-H protons. Reducing the temperature failed to resolve these resonances, possibly implying fast scrambling of the H-atoms between the [1H₁]⁻ and [1H₂]⁻ ligands.

![Scheme 2 The stoichiometry of the reaction producing 3, showing the structure of the complex and the observed deprotonation pattern of the [1H₄] substrate.](image)

A further feature of the ¹H NMR spectra of samples of 3, which were dried under vacuum prior to transfer to a glove box for analysis, is the lower than expected integral of the THF ligands. This feature is probably largely responsible for the higher than expected N analysis found for isolated samples of the complex (found 14.3% vs. 12.5%; although the C and H analyses were acceptable).

Double- and single-deprotonation of the NH₂ groups of multifunctional aliphatic and aromatic primary amines has been seen before using LiAlH₄. An example is the reaction of DippNH₂ (Dipp = 2,6-PrC₆H₄) which gives the dimer [Al{(DippNH₂)₂}{(µ-NDipp)][Li(THF)₂]. However, to the best of our knowledge the current study represents the first investigation of the reactions of LiAlH₄ with aromatic diamines. The formation of the triply-deprotonated [1H₃]⁻ trianion in 3 is similar to that seen in the reaction of 1H₄ with Sn(NMe₂)₃BuLi at room temperature, while the quadruple-deprotonation of 1H₄ (to [1⁺]) only appears to occur in the presence of the more basic reagent mixture Sb(NMe₂)₃BuLi.

Reactions of 2H₄ with LiAlH₄ proceeded in a similar manner to those with 1H₄, but the products appeared to be much less sensitive to traces of oxygen. Although a variety of reaction conditions and different reactant stoichiometries were employed, only products resulting from double deprotonation of 2H₄ could be isolated and only in the presence of chelating donor ligands. The new complexes [Al(2H₂)₂] [Li(PMDETA)(THF)]⁺ (4) and [Al(2H₂)₂][Li(TMEDA)]⁺ (5) are obtained in highest yields (48% and 53%, respectively) from the 1:2 stoichiometric reactions of LiAlH₄ with 2H₄ in THF, in presence of an excess of the Lewis base donor ligands PMDETA and TMEDA (respectively) (Scheme 3). Unlike the room temperature ¹H NMR spectrum of 3, the ¹H NMR spectra
of 4 and 5 are well resolved in the aromatic region of the \([2\text{H}_2]^2\) dianion ligands (ESI). The 1,8-naphthyl groups in both appear in the range \(\delta 5.8-6.6\), with the N-H protons being found at \(\delta 3.8\). The \(^1\text{H}\) NMR spectra of 5 also show that a significant amount of residual THF is preserved in crystalline samples of the complex after isolation under vacuum. Both C, H and N analysis and integration of the \(^1\text{H}\) NMR spectrum show that there are ca. three TMEDA molecules per THF normally found in solid samples (i.e., 1 molecule of THF for every 1.5 molecules of 5).

\[
\text{LiAIH}_4 + 2[2\text{H}_2] \rightarrow [\text{Al}(2\text{H}_2)_2]_2^+[\text{Li}(L)(L')]+ + 4\text{H}_2
\]

\[L = \text{PMDTA}; L' = \text{THF} (4) \quad L = L' = \text{TMEDA} (5)\]

Scheme 3 The reactions producing the related ion-separated complexes 4 and 5, showing the structure of the aluminate anion and the deprotonation pattern of 2H₂.

1,8-diaminonaphthalene (2H₂), particularly in its doubly deprotonated form \([2\text{H}_2]^2\), has been used extensively as a ligand in a number of transition metal complexes.\(^{15}\) However, although a large number of complexes containing N,N-disubstituted ligands of the type \([2\text{R}]^2\) (R = alkyl, aryl or silyl) have been reported for main group metals,\(^{19}\) main group metal complexes containing the parent \([2\text{H}_2]^2\) ligand are very rare\(^{17}\) and there are no previously reported examples of Group 13 metal complexes containing the \([2\text{H}_2]^2\) ligand.

Single-crystal X-ray diffraction studies of the new complexes 3, 4 and 5 were undertaken at 180(2) K. Details of the structure refinements and data collections on 3 and 4 are collected in Table 1 (Experimental Section). Since the X-ray data for 5 was of poor quality [with lowest obtained \(R(1) = 10.34\%\), despite repeated data collections] the structure of the complex is not discussed in detail here (see ESI).

\[\text{[(Al}(1\text{H}_2)_2)_2\text{Al}(1\text{H}_2)_2][\text{Li}(\text{THF})_2]_4 (3)\]

crystallizes in monoclinic space group \(P2_1/n\) and its molecular structure is illustrated in Fig. 2. The complex has an ion-paired structure resulting from the association of an aluminate \[\text{[(Al}(1\text{H}_2)_2)_2\text{Al}(1\text{H}_2)_2]^4\] tetraanion with four \(/[\text{Li}(\text{THF})_2]_4^\text{\textsuperscript{+}}\) cations. A schematic of the structure is shown in the insert to Scheme 2. The \[\text{[(Al}(1\text{H}_2)_2)_2\text{Al}(1\text{H}_2)_2]^4\] tetraanion is constructed (formally) from two \[\text{[Al}(1\text{H}_2)_2]_2^\text{3-}\] and \[\text{[Al}(1\text{H}_2)_2]^\text{2+}\] subunits which form a cyclic arrangement composed of a central eight-membered (twist-chair\(^{20}\)) \(\text{Al}_2\text{N}_4\) ring unit, using the imido-N atoms of the \[\text{[Al}(1\text{H}_2)_2]_2^\text{3-}\] fragments.

Fig. 2 (a) Molecular structure of \[\text{[(Al}(1\text{H}_2)_2)_2\text{Al}(1\text{H}_2)_2][\text{Li}(\text{THF})_2]_4 (3)\]. C-bonded H-atoms and the disordered components of the THF ligands have been omitted for clarity. Selected bond lengths (Å) and angles (°) : Al(1)-N(1) 1.846(3), Al(1)-N(2) 1.858(4), Al(1)-N(3) 1.843(3), Al(1)-N(4) 1.865(3), Al(3)-N(7) 1.869(3), Al(3)-N(8) 1.831(5), Al(3)-N(9) 1.880(3), Al(3)-N(10) 1.832(5), Al(2)-N(3) 1.818(3), Al(2)-N(5) 1.880(3), Al(2)-N(6) 1.874(3), Al(2)-N(7) 1.845(3), Al(4)-N(1) 1.826(3), Al(4)-N(9) 1.862(3), Al(4)-N(11) 1.880(3), Al(4)-N(12) 1.877(3). Li-N range 2.15(1)-2.25(1), N-Al-N (AlAlN ring) range 117.3(2)-124.9(2), N-Al-N (chelate) range 87.2(9)-90.0(2), Al-N-Al (AlAlN ring) range 119.4(2)-122.0(2); (b) The core structure of the complex, with the THF ligands and aromatic rings removed.

Fig. 3 The \[\text{Al}(1\text{H}_2)_2^2-\] and \[\text{[Al}(1\text{H}_2)_2]^2+\] subunits of 3.

This arrangement results in two distinct Al-environments \([\text{Al}(1)/\text{Al}(3)\text{ and Al}(2)/\text{Al}(4)\text{}],\) each of which have pseudo-tetrahedral metal geometries with the Al centres being bonded.
solely to N atoms. The Al-N bond lengths within 3 are in the range 1.818(3)-1.880(3) Å, with no significant differences between the amido N(H)-Al and imido N-Al bonds being discernible.\textsuperscript{21} The tetraanion of 3, containing four Al-atoms, is the largest species of this type to be reported. Previously, amido/imido-aluminate anions containing a maximum of two Al atoms have been observed.\textsuperscript{7b,c}

A surprising feature of the structural arrangement of 3 is the presence of two Li\textsuperscript{+} coordination environments. Although all of the Li\textsuperscript{+} cations are pseudo-tetrahedral, Li(1) and Li(4) are each bound to one amido N(H) atom of a [Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] and one of a [Al(IIH\textsubscript{2})\textsuperscript{1}\textsuperscript{+}] fragment, while Li(2) and Li(3) are bonded to the imido-N atom of a [Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] unit and an amido N(H) atom of a [Al(IIH\textsubscript{2})\textsuperscript{1}\textsuperscript{+}] unit. The N-Li bond lengths are in the range 2.15(1) - 2.25(1) Å, within the normal range observed previously.\textsuperscript{21} The reason for the unsymmetrical coordination of the Li\textsuperscript{+} cations in 3 can be traced to the disposition of the C\textsubscript{6}H\textsubscript{4} rings of the [Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] subunits at either end of the [Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}[Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] tetraanion. As can be seen from Fig. 2b, showing the core structure of the complex, the [Al(IIH\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] subunits have virtual mirror symmetry with respect to the central Al\textsubscript{4}N\textsubscript{4} ring, which limits the availability of the imido-N atoms to coordinate all of the Li\textsuperscript{+} cations.

![Diagram of the structure of (a) the anions and (b) the cation of [Al(2H\textsubscript{2})\textsuperscript{3}\textsuperscript{-}] [Li(PMDETA)(THF)]\textsuperscript{+} (4). C-bonded H-atoms have been omitted for clarity. Bound H atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Al(1)-N(1) 1.821(3), Al(1)-N(2) 1.814(3), Al(1)-N(3) 1.831(3), Al(1)-N(4) 1.815(3), N-Al-N (chelate) range 95.2(1)-95.6(1)°, N-Al-N (between [2H\textsubscript{2}]\textsuperscript{2}\textsuperscript{-} ligands) range 116.2(2)-118.3(2)°, C-N-Al range 127.6(2)-129.6(3).](image-url)
Experimental

General Experimental Procedures

All compounds described in this paper are air and moisture sensitive. Preparations were performed on a double-manifold vacuum line under a nitrogen atmosphere. The products were isolated and stored with the aid of a nitrogen-filled glove box (Saffron type b), equipped with Cu and molecular sieve columns in order to remove O2 and moisture, respectively.

TMEDA and PMDETA (Aldrich) were distilled from Na and stored under argon. All 1H and 13C NMR spectra were recorded using a Bruker DPX 500 MHz NMR spectrometer. Elemental (C, H, N) analyses were obtained using an Exeter CE-440 Elemental Analyser. Samples for analysis (1-2 mg) were placed in pre-weighed, airtight aluminium boats in the glove box prior to analysis.

Synthesis of [[Al(1H2)2]2[Li(THF)]2] (3): LiAlH4 (23 mg, 0.61 mmol) was added to a solution of 1,2-phenylenediamine (100 mg, 0.92 mmol) in 5 ml THF and the mixture stirred for 16h at room temperature. The solution was filtered into a crystallization tube (20 mm diameter) and the volume of solvent reduced in vacuo to approximately 1 ml. Hexane (10 ml) was then carefully layered onto the solution and the tube was sealed and allowed to remain undisturbed for one week after which time the product had solidified. The solvents were then decanted off and the solids collected and allowed to dry in the glove box. Yield 99 mg (48 %). Found (%): C 61.3, H 7.0, N 14.3; Calcd. for C68H56AlLiN12O6: C 60.7, H 7.2, N 12.5. 1H NMR (400.1 MHz, 25 °C, D2-THF), δ/ppm = 6.13 (br s, 8H, [ArH(NH)(N)]3), 6.05 (br s, 8H, [ArH(NH)(N)]3), 5.9-6.5 (br m, 8H, ArH(NH)), 3.60 (m, THF), 3.05 (br s, 8H, NH), 1.77 (m, THF); 13C[1H] NMR (400.1 MHz, 25 °C, D8-THF), δ/ppm = 145.5 (br m, ArH), 114.5 (br m, ArH), 110.8 (br m, ArH), 68.2 (m, THF), 26.4 (THF).

Synthesis of [[Al(2H2)2][Li(PMDETA)(THF)]* (4): LiAlH4 (12 mg, 0.32 mmol) was added to a solution of 1,8-diaminonaphthalene (100 mg, 0.63 mmol) in 5 ml THF containing 0.5 ml PMDETA (2.4 mmol). The mixture was heated to reflux for 1h and sufficient hot THF (approx. 3 ml) was added to dissolve the precipitate which had formed. The solution was filtered whilst hot and allowed to cool slowly to room temperature resulting in crystallization of the product. The mother liquor was decanted off and the crystals allowed to dry in the glove box. Yield 90 mg (48 %). Found (%): C 67.0, H 7.9, N 16.6; Calcd. for C33H32AlLiNO: C 67.0, H 8.0, N 16.6. 1H NMR (400.1 MHz, 25 °C, D2-THF), δ/ppm = 6.62 (t, J = 8.0 Hz, 4H, ArH), 6.33 (dd, J = 8.0, 1.2 Hz, 4H, ArH), 5.86 (dd, J = 8.0, 1.2 Hz, 4H, ArH), 3.81 (s, 4H, ArNH), 3.61 (m, 4H, THF), 2.39 (td, J = 6.8, 0.8 Hz, 4H, PMDETA CH3), 2.28 (td, J = 6.8, 0.8 Hz, PMDETA CH3), 2.19 (s, 3H, PMDETA CH3), 2.14 (s, 12H, PMDETA CH3). 13C[1H] NMR (400.1 MHz, 25 °C, D8-THF), δ/ppm = 155.8

X-Ray Crystallography

Data for all complexes were collected on a Nonius KappaCCD diffractometer and solved by direct methods and refined by full-matrix least squares on F2. All of the THF molecules in the structure of 3 [except those attached to Li(4i)] exhibit site disorder in which the C-atoms of the backbone of the ligands were modelled over two 50:50 sites.
