An unusual finding in a 57-year-old woman with new onset hypertension and a diastolic murmur

CLINICAL INTRODUCTION

A 57-year-old woman presented to our clinic with breathlessness brought on while walking uphill. She had been recently diagnosed with systemic hypertension. There was no known family history of cardiac disease, or prior smoking habit. On examination, pulse was 73 bpm and blood pressure 155/73 mm Hg, which was asymmetrical in her arms. Auscultation revealed a readily audible early diastolic murmur in the aortic area and bilateral subclavian bruits. ECG showed sinus rhythm with no abnormality. Transthoracic echocardiography demonstrated mild-to-moderate aortic regurgitation, and normal left ventricular size and function. The ascending aorta was mildly dilated (41 mm), with para-aortic thickening noted. Owing to the abnormal appearance of the aortic wall, cardiac MRI, and subsequently 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) scan was performed (figure 1).

QUESTION

Which complication of the underlying disease is evident in figure 1, panel C?
A. Aortic aneurysm
B. Aortic dissection
C. Aortic thrombus
D. Coronary artery aneurysm
E. Coronary sinus fistula

For the answer see page 1771

Figure 1 Transthoracic echocardiogram in high left parasternal long-axis view (A); cardiac MRI with black-blood sequence in sagittal (B) and axial planes (C); fused 18F-fluorodeoxyglucose positron emission tomography-MRI (D). The asterisk in 1A refers to para-aortic thickening.
An unusual finding in a 57-year-old woman with new onset hypertension and a diastolic murmur

For the question see page 1762

ANSWER: D

Cardiac MRI shows marked circumferential proximal para-aortic soft tissue thickening, measuring 8.5 mm. Strikingly, a large (8 mm) coronary artery aneurysm involving the left main stem and proximal left anterior descending artery is also evident on MRI. The coronary artery aneurysm (arrows) was further characterised using CT angiography, shown in axial view and three-dimensional volume-rendered CT (figure 2). There was also a non-calcified atherosclerotic plaque at the transition of the aneurysmal and tubular left anterior descending artery, and bilateral subclavian stenoses. 

$^{18}$F-FDG PET images demonstrated severe inflammation of the proximal aorta (maximum standardised uptake value 6.7) and the coronary aneurysm. The underlying unifying diagnosis was vasculitis, most likely Takayasu’s arteritis in type. While other vasculitides can cause aortitis, coronary involvement and presence of subclavian stenoses support the diagnosis of Takayasu’s arteritis. This large-vessel granulomatous vasculitis typically affects the aorta and its main branches, causing stenosis at the vessel origin. Up to 40% of patients with Takayasu’s arteritis also exhibit cardiac complications, which include aortic regurgitation, accelerated atherosclerosis, and, rarely, coronary artery aneurysm. Multi-modal cardiac imaging plays an important role in diagnosis and therapeutic monitoring.
