1. General experimental details

All batch reactions were performed using oven-dried glassware (200 °C) under an atmosphere of argon unless otherwise stated. All flow reactions were performed using a Uniqsis FlowSyn platform^[1] or a Vapourtec R2+R4 system.^[2] Solvents were freshly distilled over sodium benzophenone ketyl (THF, Et₂O) or calcium hydride (acetone, MeCN, MeOH, CH₂Cl₂, CHCl₃, toluene, hexane and EtOAc). Additional anhydrous solvents were obtained from commercial sources and used directly (DMF, DMA, DMSO and 1,4-dioxane). DIPEA and Et₃N were freshly distilled over calcium hydride and stored over 4 Å molecular sieves. All reagents were obtained from commercial sources and used without further purification.

Flash column chromatography was performed using high-purity grade silica gel (Merck grade 9385) with a pore size 60 Å and 230–400 mesh particle size under air pressure. Analytical thin layer chromatography (TLC) was performed using silica gel 60 F₂₅₄ pre-coated glass backed plates and visualized by ultraviolet radiation (254 nm) and/or potassium permanganate solution as appropriate.

¹H NMR spectra were recorded on a 600 MHz Avance 600 BBI Spectrometer as indicated. Chemical shifts are reported in ppm with the resonance resulting from incomplete deuteration of the solvent as the internal standard (CDCl₃: 7.26 ppm). ¹³C NMR spectra were recorded the same spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with the solvent resonance as the internal standard (¹³CDCl₃: 77.16 ppm, t). ¹⁹F NMR spectra were recorded on a 376 MHz Avance III HD Spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with CFCl₃ as the external standard (CFCl₃: 0.00 ppm). Data are reported as follows: chemical shift δ/ppm, integration (¹H only), multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, qn = quintet, sept = septet, oct = octet, br = broad, m = multiplet or combinations thereof; ¹³C signals are singlets unless otherwise stated), coupling constants J in Hz, assignment. Spectra are assigned as fully as possible, using ¹H-COSY, DEPT-135, HMQC and HMBC where appropriate to facilitate structural determination. Signals that cannot be unambiguously assigned are reported with all possible assignments separated by a slash (e.g. H1/H2) or descriptions of their environments (e.g. ArH, NH, OH). Multiple signals arising from diastereotopic or (pseudo)axial/equatorial positions are suffixed alphabetically (e.g. H1a, H1b). Overlapping signals that cannot be resolved are reported with their assignments denoted in list format (e.g. H1, H2 and H3). ¹H NMR signals are reported to 2 decimal places and ¹³C signals to 1 decimal place unless rounding would produce a value identical to another signal. In this case, an additional decimal place is reported for both signals concerned.

Infrared spectra were recorded neat as thin films on a Perkin-Elmer Spectrum One FTIR spectrometer and selected peaks are reported (s = strong, m = medium, w = weak, br = broad).

High resolution mass spectrometry (HRMS) was performed using positive electrospray ionisation (ESI+), on either a Waters Micromass LCT Premier spectrometer or performed by the Mass Spectrometry Service for the Chemistry Department at the University of Cambridge. All *m/z* values are reported to 4 decimal places and are within ± 5 ppm of theoretical values.

Specific optical rotation was recorded on a Perkin-Elmer Model 343 digital polarimeter, using a Na/Hal lamp set at 589 nm and with a path length of 100 mm. [α]_D values were measured using spectroscopy grade solvent at the specified concentration (in g/100 mL) and temperature, with units of deg 10⁻¹ cm² g⁻¹.

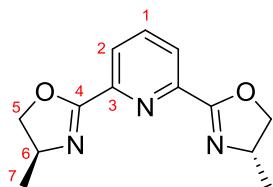

Melting points were recorded on a Stanford Research Systems OptiMelt Automated Melting Point System calibrated against vanillin (m.p. 83 °C), phenacetin (m.p. 136 °C) and caffeine (m.p. 237 °C).

Chiral HPLC analysis was conducted on an Agilent 1100 Series Chromatography system using mixtures of hexane/isopropanol as eluent on Chiraldak AS, Chiraldak OD-H, ChiralART SA or ChiralART SC columns.

2. Synthetic procedures and characterisation for new ligands

2.1. PyBOX ligands

General procedure for PyBOX synthesis:^[3] A solution of the appropriate 2,6-pyridinedicarbonitrile (1.0 mmol, 1 equiv.), the appropriate amino alcohol (2.0 mmol, 2 equiv.) and zinc(II) triflate (36 mg, 0.1 mmol, 0.1 equiv.) in toluene (15 mL) was heated under reflux for 48 h. The reaction mixture was then cooled to r.t. and diluted with EtOAc (10 mL). The organic layer was washed with brine (3 × 25 mL), saturated aqueous NaHCO₃ solution (3 × 25 mL), dried (MgSO₄) and evaporated under reduced pressure. The residue was further purified by silica gel column chromatography or recrystallisation as appropriate.

2,6-bis((S)-4-methyl-4,5-dihydrooxazol-2-yl)pyridine: Following the general procedure for PyBOX synthesis, using 2,6-pyridinedicarbonitrile (0.129 g, 1.0 mmol, 1 equiv.) and (S)-2-aminopropan-1-ol (0.286 g, 2.0 mmol, 2 equiv.), purified by silica gel column chromatography (eluent: 5% MeOH/CH₂Cl₂) provided the title compound as a white amorphous solid (0.022 g, 0.09 mmol, 9%), m.p. 148–151 °C (lit. m.p.^[4] 163.0–165.5 °C, on material with 0.25 mol H₂O). Data are consistent with a reported example.^[4]

¹H NMR (600 MHz, CDCl₃): δ 8.17 (d, *J* = 7.8 Hz, 2 H, H2), 7.86 (t, *J* = 7.8 Hz, 1 H, H1), 4.61 (dd, *J* = 9.5, 8.3 Hz, 2 H, H5a), 4.43 (ddq, *J* = 9.5, 8.3, 6.7 Hz, 2 H, H6), 4.07 (t, *J* = 8.3 Hz, 2 H, H5b), 1.37 (d, *J* = 6.7 Hz, 6 H, H7).

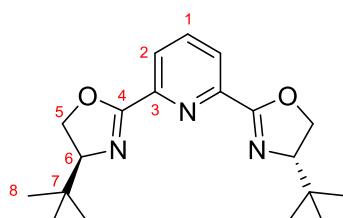

¹³C NMR (150 MHz, CDCl₃): δ 162.4 (C4), 147.0 (C3), 137.4 (C1), 125.8 (C2), 74.9 (C5), 62.4 (C6), 21.5 (C7).

FTIR (v_{max}, cm⁻¹): 2971 (m), 2900 (w), 1641 (s), 1575 (s), 1531 (w), 1459 (m), 1385 (m), 1305 (w), 1269 (w), 1246 (w), 1171 (w), 1119 (m), 1068 (s), 973 (s), 945 (m), 831 (w).

HRMS (ESI): calculated for C₁₃H₁₆N₃O₂ [M+H]⁺ 246.1237, found 246.1231.

R_f = 0.26 (5% MeOH/CH₂Cl₂).

[α]_D^{28.3} = -127.6 (CHCl₃, c = 0.5); lit.^[4] [α]_D = -131.8 (CHCl₃, c = 0.72).

2,6-bis((S)-4-(tert-butyl)-4,5-dihydrooxazol-2-yl)pyridine (L2): Following the general procedure for PyBOX synthesis, using 2,6-pyridinedicarbonitrile (0.387 g, 3.0 mmol, 1 equiv.) and L-*tert*-leucinol (0.703 g, 6.0 mmol, 2 equiv.), after extraction and evaporation provided the title compound as a white crystalline solid (0.970 g, 2.9 mmol, 98%), m.p. 236–238 °C. Data are consistent with a reported example.^[5]

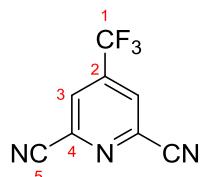

¹H NMR (600 MHz, CDCl₃): δ 8.25 (d, *J* = 7.8 Hz, 2 H, H2), 7.84 (t, *J* = 7.8 Hz, 1 H, H1), 4.47 (dd, *J* = 10.3, 8.6 Hz, 2 H, H5a), 4.32 (t, *J* = 8.6 Hz, 2 H, H6), 4.10 (dd, *J* = 10.3, 8.6 Hz, 2 H, H5b), 0.96 (s, 18 H, H8).

¹³C NMR (150 MHz, CDCl₃): δ 162.3 (C4), 147.1 (C3), 137.2 (C1), 126.0 (C2), 76.5 (C6), 69.6 (C5), 34.1 (C7), 26.1 (C8).

FTIR (v_{max}, cm⁻¹): 2957 (m), 2902 (w), 2869 (w), 1641 (s), 1590 (w), 1569 (m), 1475 (m), 1459 (m), 1417 (w), 1395 (m), 1377 (s), 1363 (s), 1319 (w), 1276 (m), 1212 (m), 1195 (w), 1153 (w), 1106 (s), 1075 (m), 1057 (m), 1032 (m), 997 (m), 967 (m), 956 (m), 931 (m), 899 (w), 865 (w), 841 (m), 757 (m).

HRMS (ESI): calculated for C₁₉H₂₇N₃O₂Na [M+Na]⁺ 352.1995, found 352.2005.

[α]_D^{24.0} = -115.0 (CH₂Cl₂, c = 1.0); lit.^[5] [α]_D²⁷ = -118 (CH₂Cl₂, c = 0.5).

4-(trifluoromethyl)pyridine-2,6-dicarbonitrile: To a 20 mL microwave vial was added 2,6-dichloro-4-(trifluoromethyl)pyridine (1.080 g, 5.0 mmol, 1.0 equiv.), zinc(II) cyanide (0.646 g, 5.5 mmol, 1.1 equiv.), zinc powder (65 mg, 1.0 mmol, 0.2 equiv.), palladium(II) trifluoroacetate (83 mg, 0.25 mmol, 0.05 equiv.), *rac*-2-(di-*tert*-butylphosphino)-1,1'-binaphthyl (0.199 g, 0.50 mmol, 0.1 equiv.) and anhydrous DMA (20 mL). The mixture was placed under vacuum and backfilled with argon (three cycles), stirred at r.t. for 20 min, then subsequently heated to 95 °C for 16 h. The mixture was then cooled to r.t. and filtered through a pad of Celite, eluting with EtOAc. The solvents were removed by vacuum distillation (6-10 mmHg) and the residue purified by silica gel column chromatography (eluent: 10% EtOAc/hexane) to provide the title compound as a pale yellow amorphous solid (0.620 g, 3.1 mmol, 63%), m.p. 103-104 °C.

¹H NMR (600 MHz, CDCl₃): δ 8.12 (q, *J* = 0.6 Hz, 2 H, H3).

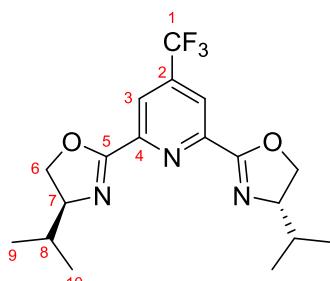

¹³C NMR (150 MHz, CDCl₃): δ 142.0 (q, *J* = 36.8 Hz, C2), 136.7 (C4), 127.0 (q, *J* = 3.4 Hz, C3), 120.9 (q, *J* = 274.8 Hz, C1), 114.5 (C5).

2.2. PyBIM ligands

General procedure for PyBIM synthesis:^[13] To a mixture of the appropriate amide precursor (5.0 mmol, 1 equiv.) in anhydrous CHCl₃ (35 mL) was added thionyl chloride (2.1 mL, 28.8 mmol, 5.8 equiv.) at 0 °C. The mixture was then heated under reflux for 5 h. Phosphorus pentachloride (2.19 g, 10.5 mmol, 2.1 equiv.) was then added in one portion and the mixture stirred under reflux for 16 h. The solution was then stripped of volatiles and the residue redissolved in anhydrous CHCl₃ (35 mL) to use as a stock solution of the imidoyl chloride intermediate.

(N.B. The imidoyl chlorides are highly water sensitive, reacting with adventitious water from the atmosphere to form the corresponding amides – it is recommended to use the solution immediately. The quality of the solution can be checked by taking a small aliquot, ca. 0.02 mL, removing all solvent under high vacuum and analysing by ¹H NMR.)

To a 5 mL microwave vial was added a solution of the imidoyl chloride in CHCl₃ (3.5 mL, 0.5 mmol, 1 equiv.), triethylamine (0.52 mL, 3.6 mmol, 7.2 equiv.) and the appropriate aniline/amine (1.1 mmol, 2.2 equiv.). The vial was sealed and stirred at r.t. or 60 °C for the allotted time. The mixture was diluted with CH₂Cl₂ (10 mL) then quenched with 1 M aqueous NaOH solution (10 mL). The organic layer was separated and the aqueous layer extracted further with CH₂Cl₂ (3 × 10 mL). The combined organic extracts were dried (MgSO₄) and evaporated under reduced pressure. The residue was then purified by silica gel column chromatography.

N²,N⁶-bis((S)-1-hydroxy-3-methylbutan-2-yl)pyridine-2,6-dicarboxamide: To a stirred solution of L-valinol (2.06 g, 20.0 mmol, 2 equiv.) and triethylamine (2.79 mL, 20.0 mmol, 2 equiv.) in anhydrous CH₂Cl₂ (50 mL) was added portionwise pyridine-2,6-dicarbonyl chloride (2.04 g, 10.0 mmol, 1 equiv.) at 0 °C. The mixture was warmed to r.t. and stirred further for 16 h. Water (50 mL) was added and the organic layer separated. 3. Synthetic procedures and characterisation for alkyne starting materials

General procedure for propargylamide synthesis via EDC coupling: To a solution of the appropriate carboxylic acid (5.0 mmol, 1.0 equiv.) in CH₂Cl₂ (20 mL) was added, if stated, DIPEA (1.05 mL, 6.0 mmol, 1.2 equiv.). EDC hydrochloride (1.15 g, 6.0 mmol, 1.2 equiv.) was added and stirred for 2 min, then HOBr (0.743 g, 5.5 mmol, 1.1 equiv.) was added and stirred for a further 2 min. Propargylamine (0.35 mL, 5.5 mmol, 1.1 equiv.) was then added and the mixture stirred at r.t. for 16 h. The mixture was diluted with CH₂Cl₂ (20 mL), washed with saturated aqueous Na₂CO₃ solution (25 mL) then 1 N aqueous HCl solution (20 mL). The organic phase was then dried (MgSO₄) and evaporated under reduced pressure. The residue was purified by silica gel column chromatography to provide the desired propargylamide.

General procedure for propargylamide synthesis via acyl chlorides: To a solution of the propargylamine (0.35 mL, 5.5 mmol, 1.1 equiv.) in CH₂Cl₂ (10 mL) was added Et₃N (0.77 mL, 5.5 mmol, 1.1 equiv.) and DMAP (61.1 mg, 0.5 mmol, 0.1 equiv.). The appropriate acyl chloride (5.0 mmol, 1.0 equiv.) was then added (dropwise if liquid, as a solution in 2 mL CH₂Cl₂ if solid) and the mixture stirred at r.t. for 16 h. The mixture was diluted with CH₂Cl₂ (10 mL) and treated with 1 N aqueous NaOH solution (20 mL). The organic layer was separated and the aqueous layer extracted further with CH₂Cl₂ (3 × 10 mL). The combined organic extracts were dried (MgSO₄) then evaporated under reduced pressure. The residue was purified by silica gel column chromatography to provide the desired propargylamide.

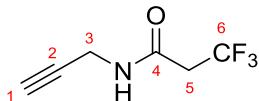

4-methyl-N-(prop-2-yn-1-yl)benzenesulfonamide (3a): To a solution of propargylamine (3.2 mL, 50.0 mmol, 1 equiv.) in CH₂Cl₂ (125 mL) at 0 °C was added Et₃N (17.4 mL, 125.0 mmol, 2.5 equiv.) then *p*-toluenesulfonyl chloride (9.53 g, 50.0 mmol, 1 equiv.) portionwise. The mixture was stirred at r.t. for 16 h. The reaction mixture was then diluted with Et₂O (500 mL) and the organic phase washed with 1 N aqueous HCl solution (300 mL), saturated aqueous NH₄Cl solution (300 mL), dried (MgSO₄) and evaporated under reduced pressure. The residual precipitate was triturated with hexane (3 × 25 mL) to provide the title product as an off-white amorphous solid (9.55 g, 45.6 mmol, 91%), m.p. 74–76 °C (lit. m.p.^[26] 74–75 °C). Scheme S1: List of ligands tested for the asymmetric allenylation of alkyne **3a**.

The absence of any enantioselectivity for the bidentate ligands, particularly the two BOX ligands tested, appears to imply that the use of *tridentate* ligands are essential for asymmetric *disubstituted* allene synthesis (Scheme S1). It should be noted that during our tests with these tridentate ligands for the allenylation of ketone-derived diazo compounds and terminal alkynes, no enantioselectivity was observed. In contrast, Wang *et al.* describe the use of *bidentate* BOX ligands for *trisubstituted* allene synthesis. Taken together, these results seem to suggest that these ligand systems are complementary to each other – with *tridentate* ligands allowing asymmetric induction for *disubstituted* allenes and *bidentate* ligands allowing asymmetric induction for *trisubstituted* allenes.

For the PyBOX ligands, enantioselectivities were best when the 4-position group on the oxazoline was a secondary alkyl group (68% *ee* with $^{\text{t}}\text{Pr}$ and cyclohexyl). A primary alkyl group does not provide enough steric bulk (45% *ee* with Me), whereas a tertiary alkyl group (50% *ee* with $^{\text{i}}\text{Bu}$, **L2**) perhaps diverts the binding mode of the oxazoline units to species that are poorer at inducing enantioselectivity, by partially favouring coordination to oxygen rather than nitrogen (Scheme S2a).

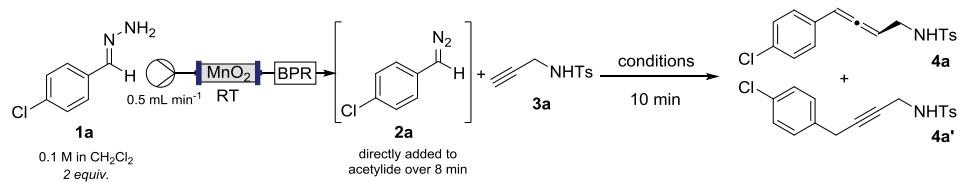

Scheme S2: Proposed rationale for trends in enantiocontrol for PyBOX and PyBIM ligands.

Comparison of the (*S*)-Ph-PyBOX result (46% *ee*) with the (*S,S*)-diPh-PyBOX result (80% *ee*) lends further evidence for this hypothesis, since coordination to the oxygen atom for the latter case maintains steric bulk close to the reactive center (Scheme S2b). A similar trend is observed when comparing (*S*)- $^{\text{i}}\text{Pr}$ -PyBOX (**L1**, 68% *ee*) to (*S,S*)-di $^{\text{i}}\text{Pr}$ -PyBOX (**L3**, 84% *ee*).

For the PyBIM ligands, a tertiary alkyl group (86% *ee* for (*S*)- $^{\text{t}}\text{Bu}$ -NBn-PyBIM) was better than a secondary alkyl group (67% *ee* for (*S*)- $^{\text{i}}\text{Pr}$ -NBn-PyBIM) for inducing enantioselection, contrasting with the trend seen with the PyBOX ligands. Attempting to install $^{\text{i}}\text{Pr}$ groups in a similar fashion to that of (*S,S*)-diPh-PyBOX only causes erosion in enantioselectivity (19% *ee*), suggesting that the imidazoline units do not act as ambidentate ligands as proposed for the oxazoline units of PyBOX ligands (Scheme S2c).

6. Synthetic procedures and characterisation for asymmetric allenylation

Stock solution of L9-CuI: To a mixture of 2,6-bis((S)-4-(*tert*-butyl)-1-(4-(pentafluorosulfanyl)phenyl)-4,5-dihydro-1*H*-imidazol-2-yl)pyridine (**L9**) (0.549 g, 0.75 mmol) and copper(I) iodide (95.2 mg, 0.50 mmol) was added 1,4-dioxane (50 mL) and Et₃N (1.39 mL, 10.0 mmol). The mixture was stirred at r.t. for 2 h, resulting in a brown-red solution of the ligand/copper complex. The solution was stored at -20 °C under Ar as a precaution.

General procedure for racemic allenylation:^[35]

Conditioning phase: A solution of hydrazone (0.1 M) and DIPEA (0.2 M) in CH₂Cl₂ was passed through a column reactor (Omnifit® column, 6.6 mm i.d. × 50 mm length), packed with activated MnO₂ (0.86 g), at a flow rate of 0.5 mL min⁻¹ for 20 min and the reactor output was monitored using a FlowIR® device (SiComp head, 2100-2000 cm⁻¹). The flow was switched to solvent (DIPEA, 0.2 M in CH₂Cl₂) for 10 min. The column was then ready for the generation of the diazo compound.

Generation phase: A 5 mL microwave vial was charged with the appropriate alkyne (0.2 mmol, 1.0 equiv.), copper (I) iodide (3.9 mg, 0.02 mmol, 0.1 equiv.), 1,4-dioxane (2 mL) and Et₃N (0.05 mL, 0.4 mmol, 2 equiv.) and pre-mixed for 10 min. A solution of hydrazone (0.1 M) and DIPEA (0.2 M) in CH₂Cl₂ was passed through the pre-conditioned column reactor (Omnifit® column, 6.6 mm i.d. × 50 mm length), packed with activated MnO₂ (0.86 g), at a flow rate of 0.5 mL min⁻¹. When the FlowIR® showed that the intensity of the diazo peak was stable, 3 mL of the output (1.5 equiv. with respect to the hydrazone) was directly added into the reaction vial (over 6 min) containing the copper acetylide and the reaction mixture further stirred at r.t. for 10 min. The mixture was then filtered through a pad of Celite, eluting with Et₂O, and the filtrate evaporated under reduced pressure. The residue was immediately purified by silica gel column chromatography to provide the desired di-substituted allene product.

Any excess diazo compound produced during the conditioning phase or the generation phase before steady-state was reached was gently quenched by directing the output of the flow reactor into a stirred suspension of copper (I) iodide (0.10 g) in MeOH (25 mL).

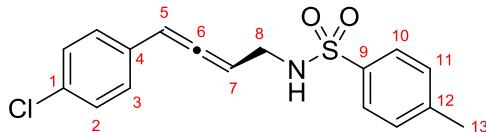

General procedure for asymmetric allenylation:

Conditioning phase: A solution of hydrazone (0.1 M) and DIPEA (0.2 M) in CH₂Cl₂ was passed through a column reactor (Omnifit® column, 6.6 mm i.d. × 50 mm length), packed with activated MnO₂ (0.86 g), at a flow rate of 0.5 mL min⁻¹ for 20 min and the reactor output was monitored using a FlowIR® device (SiComp head, 2100-2000 cm⁻¹). The flow was switched to solvent (DIPEA, 0.2 M in CH₂Cl₂) for 10 min. The column was then ready for the generation of the diazo compound.

Generation phase: To a 5 mL microwave vial was added the appropriate alkyne (0.2 mmol, 1.0 equiv.), then an aliquot of the vigorously stirred **L9**-CuI stock solution (2.05 mL, containing 0.15 equiv. ligand, 0.1 equiv. CuI and 2 equiv. Et₃N) was added. The mixture was pre-mixed at r.t. for 10 min, forming a clear red-orange homogeneous solution of the copper acetylide-ligand complex.

A solution of hydrazone (0.1 M) and DIPEA (0.2 M) in CH₂Cl₂ was passed through the pre-conditioned column reactor (Omnifit® column, 6.6 mm i.d. × 50 mm length), packed with activated MnO₂ (0.86 g), at a flow rate of 0.5 mL min⁻¹. When the FlowIR® showed that the intensity of the diazo peak was stable, 4 mL of the output (2.0 equiv. with respect to the hydrazone) was directly added into the reaction vial (over 8 min) containing the copper acetylide-ligand complex and the reaction mixture further stirred at r.t. for 10 min. The solution was evaporated under reduced pressure and the residue taken up in Et₂O (5 mL). The mixture was then filtered through a pad of Celite, eluting with Et₂O, and the filtrate evaporated under reduced pressure. The residue was immediately purified by silica gel column chromatography to provide the desired allene (and alkyne) cross-products.

Any excess diazo compound produced during the conditioning phase or the generation phase before steady-state was reached was gently quenched by directing the output of the flow reactor into a stirred suspension of copper (I) iodide (0.10 g) in MeOH (25 mL).

(R)-3,3,3-trifluoro-N-(4-(4-iodophenyl)buta-2,3-dien-1-yl)propanamide (4w): Following the general procedure for asymmetric allenylation using 3,3,3-trifluoro-N-(prop-2-yn-1-yl)propanamide (37.1 mg, 0.2 mmol) and (4-iodobenzylidene)hydrazine, purified by silica gel column chromatography (eluent: 70% Et₂O/hexane) provided the title compound as an off-white amorphous solid (37.1 mg, 0.097 mmol, 49%, 95% ee), m.p. 131-132 °C.

Scale up to 5 mmol was possible using a slightly modified procedure as follows: To a stirred **L9**-CuI solution in a 250 mL RBF (prepared on the same scale as stated for the stock solution

– 51.4 mL, containing 0.15 equiv. ligand, 0.1 equiv. CuI and 2 equiv. Et₃N) was added was added 3,3,3-trifluoro-*N*-(prop-2-yn-1-yl)propanamide (0.825 g, 5.0 mmol, 1.0 equiv.). The mixture was pre-mixed at r.t. for 10 min, forming a clear red-orange homogeneous solution of the copper acetylide-ligand complex. Solutions of hydrazone (0.1 M) and DIPEA (0.2 M) in CH₂Cl₂ were passed through eight pre-conditioned column reactors concurrently (Omnifit® column, 6.6 mm i.d. × 50 mm length), packed with activated MnO₂ (0.86 g), at a flow rate of 0.5 mL min⁻¹ each. When the FlowIR® showed that the intensity of the diazo peak was stable, 12.5 mL of each output stream from the eight columns (2.0 equiv. total with respect to the hydrazone) was directly added into the reaction vial (over 25 min) containing the copper acetylide-ligand complex and the reaction mixture further stirred at r.t. for 10 min. The solution was evaporated under reduced pressure and the residue taken up in CH₂Cl₂ (50 mL). The mixture was washed with concentrated ammonium hydroxide/saturated aqueous NH₄Cl solution (1:9, 50 mL), then the organic layer dried (MgSO₄) and evaporated under reduced pressure. The residue was immediately purified by silica gel column chromatography (eluent: 70% Et₂O/hexane) to provide the title compound as an off-white amorphous solid (0.889 g, 2.33 mmol, 47%, 95% ee).
