1. General experimental details

All batch reactions were performed using oven-dried glassware (200 °C) under an atmosphere of argon unless otherwise stated. All flow reactions were performed using a Vapourtec E-series system.^[1] Solvents were freshly distilled over sodium benzophenone ketyl (Et₂O, THF) or calcium hydride (EtOAc, acetone, MeOH, CH₂Cl₂ and toluene). Additional anhydrous solvents were obtained from commercial sources and used directly (DMSO and DCE). DIPEA was freshly distilled over calcium hydride and stored over 4 Å molecular sieves. ⁷BuLi was titrated using BHT and 1,10-phenanthroline as indicator prior to use. All reagents were obtained from commercial sources and used without further purification.

Flash column chromatography was performed using high-purity grade silica gel (Merck grade 9385) with a pore size 60 Å and 230–400 mesh particle size under air pressure. Analytical thin layer chromatography (TLC) was performed using silica gel 60 F₂₅₄ pre-coated glass backed plates and visualised by ultraviolet radiation (254 nm) and/or potassium permanganate solution as appropriate.

¹H NMR spectra were recorded on a 600 MHz Avance 600 BBI Spectrometer as indicated. Chemical shifts are reported in ppm with the resonance resulting from incomplete deuteration of the solvent as the internal standard (CDCl₃: 7.26 ppm; MeOD-*d*₄: 3.31 ppm, qn; MeCN-*d*₃: 1.94 ppm, qn; D₂O: 4.79 ppm). ¹³C NMR spectra were recorded the same spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with the solvent resonance as the internal standard (¹³CDCl₃: 77.16 ppm, t; MeOD-*d*₄: 49.00 ppm, sept; MeCN-*d*₃: 1.32 ppm, sept). ¹⁹F NMR spectra were recorded on a 376 MHz Avance III HD Spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with CFCl₃ as the external standard (CFCl₃: 0.00 ppm). ³¹P NMR spectra were recorded on an Avance 600 BBI Spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with 85% phosphoric acid in D₂O as the external standard (H₃PO₄: 0.00 ppm). Data are reported as follows: chemical shift δ/ ppm, integration (¹H, ¹⁹F and ³¹P), multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, qn = quintet, sept = septet, oct = octet, br = broad, m = multiplet or combinations thereof; ¹³C signals are singlets unless otherwise stated), coupling constants *J* in Hz, assignment. Spectra are assigned as fully as possible, using ¹H-COSY, DEPT-135, HSQC, HMBC and NOESY where appropriate to facilitate structural determination. Signals that cannot be unambiguously assigned are reported with all possible assignments separated by a slash (e.g. H1/H2) or descriptions of their environments (e.g. ArH, NH, OH). Multiple signals arising from diastereotopic or (pseudo)axial/equatorial positions are suffixed alphabetically (e.g. H1a, H1b). Overlapping signals that cannot be resolved are reported with their assignments denoted in list format (e.g. H1, H2 and H3). ¹H NMR signals are reported to 2 decimal places and ¹³C signals to 1 decimal place unless rounding would produce a value identical to another signal. In this case, an additional decimal place is reported for both signals concerned.

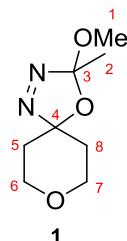

Infrared spectra were recorded neat as thin films on a Perkin-Elmer Spectrum One FTIR spectrometer and selected peaks are reported (s = strong, m = medium, w = weak, br = broad).

High resolution mass spectrometry (HRMS) was performed using positive or negative electrospray ionisation (ESI), on either a Waters Micromass LCT Premier spectrometer or performed by the Mass Spectrometry Service for the Department of Chemistry at the University of Cambridge. All *m/z* values are reported to 4 decimal places and are within ± 5 ppm of theoretical values.

Melting points were recorded on a Stanford Research Systems OptiMelt Automated Melting Point System calibrated against vanillin (m.p. 83 °C), phenacetin (m.p. 136 °C) and caffeine (m.p. 237 °C).

2. Synthetic procedures and characterisation for oxadiazolines

General procedure for oxadiazoline synthesis: A solution of the appropriate ketone (20.0 mmol, 1 equiv.) and acetic hydrazide (1.63 g, 22.0 mmol, 1.1 equiv.) in toluene (60 mL) was heated under reflux with equipped Dean-Stark apparatus for 2 h. The mixture was then evaporated under reduced pressure and the residue redissolved in MeOH (60 mL) and cooled to 0 °C. (Diacetoxyiodo)benzene (7.09 g, 22.0 mmol, 1.1 equiv.) was added portionwise, then the mixture stirred further at this temperature for 1 h. The mixture was evaporated under reduced pressure and the residue purified by silica gel column chromatography.

3. Synthetic procedures and characterisation for cross-coupled products

3.1. Protodeboronative couplings

General procedure for protodeboronative coupling: A solution of the appropriate oxadiazoline (1.0 mmol, 2 equiv.), boronic acid (0.5 mmol, 1.0 equiv.) and DIPEA (0.17 mL, 1.0 mmol, 2 equiv.) in CH_2Cl_2 (10 mL) was pumped at a flow rate of $0.125 \text{ mL min}^{-1}$ through a Vapourtec UV-150 photochemical reactor (10 mL reactor volume, FEP tubing), irradiated by a 310 nm UV lamp (9 W output power), held at 10°C and the reactor output was monitored using a FlowIR® device (SiComp head, $2100\text{-}2000 \text{ cm}^{-1}$ and $1750\text{-}1700 \text{ cm}^{-1}$). After 80 min once the reaction mixture has fully been taken up by the pump, the input was swapped to CH_2Cl_2 solvent. When the FlowIR® showed that the reaction plug was exiting the output stream (by monitoring the MeOAc C=O stretch at $1750\text{-}1700 \text{ cm}^{-1}$), the reaction plug was directed into a sealed vial containing TBAF (1.5 mL, 1.5 mmol, 3.0 equiv., 1.0 M in THF) and stirred for 16 h. The mixture was then evaporated under reduced pressure, the residue redissolved in EtOAc (5 mL) and filtered through a pad of Celite, eluting with EtOAc. The filtrate was evaporated under reduced pressure and purified by silica gel column chromatography.

4-(4-chlorophenyl)tetrahydro-2H-pyran (5a): Following the general procedure for protodeboronative coupling using 3-methoxy-3-methyl-4,8-dioxa-1,2-diazaspiro[4.5]dec-1-ene (0.186 g, 1.0 mmol) and 4-chlorophenylboronic acid (78.2 mg, 0.5 mmol), purified by silica gel column chromatography (eluent: 10% EtOAc/hexane) provided the title compound as a colourless oil (69.9 mg, 0.355 mmol, 71%). 3.2. Oxidative couplings

General procedure for oxidative coupling: A solution of the appropriate oxadiazoline (1.0 mmol, 2 equiv.), boronic acid (0.5 mmol, 1.0 equiv.) and DIPEA (0.17 mL, 1.0 mmol, 2 equiv.) in CH_2Cl_2 (10 mL) was pumped at a flow rate of $0.125 \text{ mL min}^{-1}$ through a Vapourtec UV-150 photochemical reactor (10 mL reactor volume, FEP tubing), irradiated by a 310 nm UV lamp (9 W output power), held at 10°C and the reactor output was monitored using a FlowIR® device (SiComp head, $2100\text{-}2000 \text{ cm}^{-1}$ and $1750\text{-}1700 \text{ cm}^{-1}$). After 80 min once the reaction mixture has fully been taken up by the pump, the input was swapped to CH_2Cl_2 solvent. When the FlowIR® showed that the reaction plug was exiting the output stream (by monitoring the MeOAc C=O stretch at $1750\text{-}1700 \text{ cm}^{-1}$), the reaction plug was directed into a round-bottomed flask and stirred for 16 h under air. The mixture was then evaporated under reduced pressure and the residue purified by silica gel column chromatography.

When the FlowIR® showed that the reaction mixture was starting to exit the output stream (by monitoring the MeOAc C=O stretch at $1750\text{-}1700 \text{ cm}^{-1}$), the output was directed into a flask containing pinacol (1.48 g, 12.5 mmol, 5.0 equiv.). After 400 min once the reaction mixture has fully been taken up by the pump, the input was swapped to CH_2Cl_2 solvent and the output collected until the FlowIR® showed that the reaction mixture had finished exiting the reactor, then mixture stirred further at r.t. for 16 h. 6. Differential scanning calorimetry data

Supplementary Table 1 | Differential scanning calorimetry data for oxadiazolines and selected diazo-containing compounds.

Compound	Start of decomposition / °C	Onset temperature / °C	Enthalpy of decomposition / J g ⁻¹
	94	114	-540
	93	114	-835
	102	117	-673
EtO ₂ C-N=N-CO ₂ Et	96	167	-1466
	50	79	-1762
(with 15 wt% CH ₂ Cl ₂)			

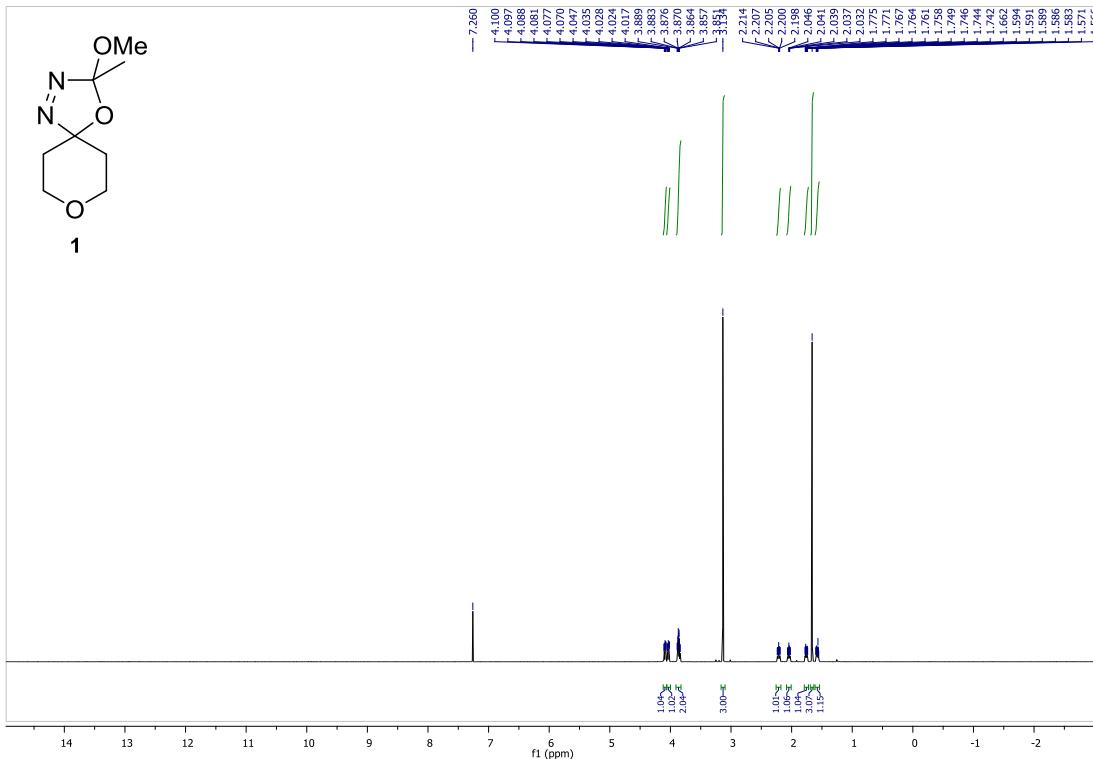

Differential scanning calorimetry (DSC) data for three oxadiazolines indicate similar decomposition and onset temperatures, of *ca.* 90-100 °C and *ca.* 115 °C respectively, significantly higher than the operating temperature of the cross-coupling reaction conditions. Enthalpies of decomposition are also lower than compared to commonly utilised diazo-containing reagents, diethyl azodicarboxylate (DEAD) and ethyl diazoacetate.^[25]
