19 **Abstract**

20 Consumption of globally traded agricultural commodities like soy and palm oil is one of the primary
21 causes of deforestation and biodiversity loss in some of the world's most species-rich ecosystems.
22 However, the complexity of global supply chains has confounded efforts to reduce impacts. Companies
23 and governments with sustainability commitments struggle to understand their own sourcing patterns,
24 while the activities of more unscrupulous actors are conveniently masked by the opacity of global
25 trade. We combine state-of-the art material flow, economic trade and biodiversity impact models to
26 produce an innovative approach for understanding the impacts of trade on biodiversity loss and the
27 roles of remote markets and actors. We do this for the production of soy in the Brazilian Cerrado, home
28 to more than 5% of the world's species. Distinct sourcing patterns of consumer countries and trading
29 companies result in substantially different impacts on endemic species. Connections between individual
30 buyers and specific hotspots explain the disproportionate impacts of some actors on endemic species
31 and individual threatened species, such as the particular impact of EU consumers on the recent habitat
32 losses for the iconic Giant Anteater (*Myrmecophaga tridactyla*). In making these linkages explicit, our
33 approach enables commodity buyers and investors to target their efforts much more closely to improve
34 the sustainability of their supply chains in their sourcing regions, while also transforming our ability to
35 monitor the impact of such commitments over time.

36

37 **Significance statement**

38 Agricultural commodity production causes significant biodiversity losses, yet our globalised supply
39 chains mean that these losses are incurred far from the places of eventual consumption. Public and
40 private sector actors are making an increasing number of commitments to reduce their environmental
41 impacts; to date, however, we have had limited understanding of a) impacts at high spatial and
42 taxonomic resolution, and b) particular consumption drivers and supply chain actors mediating trade
43 and consumption. Without these, it is difficult to devise solutions. We link three state-of-the-art
44 models to provide practical insights on the impacts of soy grown in the Brazilian Cerrado, an
45 exceptionally biodiverse savannah that hosts some 5% of the world's species.

46 **MAIN TEXT**

47 \body

48 Species are being lost at 1-2 orders of magnitude above background rates (1), with greatest losses
49 resulting from habitat conversion and degradation – particularly appropriation for agriculture (2–4).
50 Much of the impact of food crop production in biodiverse tropical regions is associated with
51 commodities destined for export (5) and as much as 80–99% of the biodiversity impact of food crop
52 consumption in industrialised countries is incurred abroad (5). Work linking biodiversity threats to
53 global financial flows at country level indicates that at least 30% of threats to globally-threatened
54 species are linked to international trade (6–8). Growing recognition of the role of global consumption
55 in driving remote environmental damage elsewhere (9–11) has led to a number of private- and public-
56 sector commitments to reduce these impacts, particularly in agricultural commodity supply chains
57 (12). However, our ability to monitor in practically useful detail whether governments or businesses
58 are making progress towards these commitments has been limited.

59 To devise and monitor solutions for sustainable production and consumption we need to know the
60 location of production areas to a high degree of spatial accuracy, and understand the biodiversity
61 impacts of production in these places. Crucially, we must also understand how impacts are connected
62 to globalised supply chains and the key actors involved (13). Progress on sustainability in supply chains
63 will need clear and measurable targets, pathways to achieve them, and accountability (12, 14).
64 Moreover, commitments of different stakeholders do not operate in isolation and when aligned can
65 reinforce one another. However, the lack of methods and data to integrate policy and business
66 perspectives prevents the design and implementation of strategies to create opportunities, or regulate
67 for more sustainable business (12, 15).

68 Here we combine state-of-the-art material flow, economic and biodiversity models that link demand,
69 trade, production and impact. We use a species-level estimate of loss, which allows us to differentiate
70 habitats that host the most vulnerable species from those that do not, but which would appear similar
71 or identical if broader classifications (e.g. ‘forest’ or ‘natural vegetation’) were used. Our results reveal
72 the impacts of agricultural commodity trade on biodiversity with unprecedented spatial, sectoral,
73 operational and taxonomic resolution.

74 We use our framework to answer four questions that together provide information for reducing
75 biodiversity losses associated with agricultural commodity demand. First, *which countries and sectors*
76 *drive impacts?* Understanding the role of specific consumption patterns and the responsibilities of
77 consumers around the globe helps inform national and international policy-making. Second, *what are*
78 *the relative roles of different commodity traders?* Detailed supply chain information can help to
79 identify and develop partnerships for solutions. Third, *what are the impacts on high-profile species and*
80 *important species assemblages?* Highly resolved information on biodiversity impacts can galvanise
81 support from consumer groups, and provide information for particular interventions around specific
82 species and risk hotspots. Fourth, *how do government and private commitments overlap?*
83 Understanding the commitments of diverse actors along the supply chain can help identify where
84 commitments coincide, and hence where actions might be aligned to reinforce one another.

85 We work through our framework using the example of Brazilian soy production. Brazil is one of the
86 world’s largest producers and exporters of soy, a globally important commodity embedded within
87 many food products - particularly because of its use as a source of protein in animal feed. In Brazil, soy
88 production is closely associated with the Cerrado (16, 17), which is the largest savannah region in
89 South America and hosts some 5% of global biodiversity, including over 4,800 plant and vertebrate
90 species found nowhere else (18). It is also one of the world’s most important frontiers of agricultural
91 expansion, with many of its species facing dire threat (16–20). Our approach produces novel insights

92 into the connections between markets, soy traders, and biodiversity losses at the point of production.
93 We consider these in the context of two high-profile collective commitments: the New York
94 Declaration on Forests, a voluntary declaration by private-, public- and third-sector parties with a
95 commitment to end forest loss by 2030 (21); and the Amsterdam Declaration, a commitment by seven
96 European countries to eliminate deforestation from agricultural commodity chains (22). These
97 commitments are a recognition that things need to change; meeting them, however, requires a
98 dramatic scaling-up of action.

99 **Results**

100 *1. Which countries and sectors are driving impacts?*

101 Information that identifies the relative roles of different countries – and sectors within them – can
102 guide coherent action amongst consumer nations to drive more sustainable production practices, and
103 provision of support to key industry actors (6). The top 10 countries importing embedded soy from the
104 Cerrado are Asian, European and North American (Table 1). However, whilst international demand,
105 especially from China, drives more than half of soy's impacts on endemic Cerrado biodiversity, the
106 domestic market is responsible for the greatest share of any country, with consumption across all of
107 Brazil driving 45% of soy-related impacts (Table 1; SI Appendix 1, Table S1). We consider these findings
108 against country-level commitments to two key declarations that aim to support companies in
109 eliminating deforestation from agricultural commodity supply chains. The first is the New York
110 Declaration on Forests. This has been signed at national- or local-government level by most of the
111 countries with the greatest soy-linked biodiversity impacts in Brazilian Cerrado, but the two countries
112 with greatest impact are notably absent (Table 1). The second is the Amsterdam Declaration, for which
113 five of the seven European signatories are among the top 10 importers of soy-driven biodiversity
114 impacts in the Cerrado: Italy, France, Germany, UK and the Netherlands (Table 1).

115 Alongside the amount of soy consumed, the impact per unit consumed also varies greatly between
116 countries. Brazil and Italy, for example, have over twice the impact per unit of soy consumed than
117 China, France or the USA. The two largest consuming countries, Brazil and China, consume similar
118 amounts of soy from the Cerrado, but show particularly high and low impacts per tonne, respectively
119 (Fig. 1a). These differences arise from differences in biodiversity losses in the municipalities from
120 which particular supply chains source soy. By combining high-resolution trade data with impacts on
121 biodiversity we find that Brazilian consumer demand was met to a greater extent by municipalities in
122 the central and southern Cerrado, where endemic richness is higher and impacts are thus greater (Fig.
123 1b-c; SI Appendix 1, Fig. S1). Chinese demand, on the other hand, was met from a more tightly
124 concentrated area in the northeast (Fig. 1c).

125 By linking direct material flows to global financial data, our approach also captures both the re-exports
126 of soy (for example, much of the soy consumed in Europe arrives via ports in the Netherlands, from
127 where it is re-exported), and the consumption of soy embedded in other products, such as in meat fed
128 on soy-derived feed. The Netherlands is a globally important trade hub, receiving much of the soy
129 coming directly from Brazil into the EU (Fig. 1d). However, tracking supply chains only to the country
130 of first import greatly overestimates the country's role as a driver of biodiversity loss, while for other
131 AD countries their role is substantially underestimated unless we consider re-exports and embedded
132 consumption of soy (Fig. 1d).

133 Sectoral drivers of biodiversity loss vary markedly between countries. In the case of AD countries –
134 particularly Germany and the UK – our results highlight the importance of 'other meat' (primarily pig
135 and poultry) consumption (Fig. 1e). For Italy and Norway on the other hand, dairy and beef sectors
136 contribute a relatively larger proportion of their biodiversity footprint.

137 **2. What are the relative roles of different traders?**
138 For the Cerrado we estimate that between 2000 and 2010, 33% of soy's impacts on endemic species
139 were in Goiás State, which occupies just 16% of the biome (SI Appendix 1, Fig. S2 & Table S2). Of 41
140 traders exporting soy from Goiás in 2011, the top 10 account for 91% of exports. Disaggregating the
141 data to municipality-level reveals the highly clustered nature of company operations (SI Appendix 1,
142 Fig. S2). The largest exporter in each municipality accounts for a mean of 97% of exports. Just five
143 traders account for all soy exports from the three most heavily affected municipalities, which together
144 incur 56% of the state's soy-driven biodiversity losses, but cover <4% of the area.

145 **3. What are the impacts on high-profile species and important species assemblages?**
146 Quantifying how consumption drives losses of charismatic, culturally important or valuable species
147 and habitats can raise the profile of environmental issues and bring into focus the tangible impacts
148 and risks of sourcing from a particular area (23). The spatial and taxonomic resolution of the
149 component models in our framework enables fine-scale, species-specific information that is typically
150 masked in national-level analyses. To illustrate this we compare impacts of soy-driven habitat loss on
151 two iconic species – the Maned Wolf (*Chrysocyon brachyurus*) and Giant Anteater (*Myrmecophaga*
152 *tridactyla*) – with impacts on endemic species, and characterise these as flows from the state in which
153 the losses occur through to the country of final consumption of the impact-linked soy (Fig. 2). This
154 reveals some striking patterns resulting from differences between the threats facing different species,
155 and from differences in sourcing between consuming countries. For example, the majority of the EU's
156 impact on the Maned Wolf is in Mato Grosso, while for Brazil it is in other states. This has implications
157 for the targeting of conservation interventions by downstream actors wanting to mitigate specific
158 impacts associated with their activities. We also find that the Giant Anteater's range has been more
159 heavily impacted by past habitat loss than that of the Maned Wolf (which better tolerates pasture and
160 arable land (17)), and that the EU has played a large role in recent losses – with impacts mostly arising
161 in Mato Grosso. Unlike for the Maned Wolf and Giant Anteater, losses in Goiás and Distrito Federal
162 dominate impacts across endemic species, largely due to the high number of endemics, particularly
163 plants, found in these states (Fig. 2; SI Appendix 1, Fig. S1).

164 **4. How do government and private commitments overlap?**
165 In 2011, companies with zero-deforestation commitments were responsible for ~80% of soy imports
166 for France, Germany and the UK (Fig. 3; SI Appendix 1, Table S3). The Netherlands, on the other hand,
167 has a more diverse supplier base with ~50% supplied by traders with zero-deforestation
168 commitments.

169 **Discussion**

170 It is encouraging that many of the countries and traders most exposed to risks of deforestation and
171 biodiversity loss in their supply chains have joined high-profile declarations to eliminate deforestation
172 from their supply chains (e.g. 21, 22, 24). However, company commitments to reducing deforestation
173 in supply chains vary widely in their detail, ambition and meaning (12, 15). Understanding alignment
174 between government and trader commitments will help identify where action should be focused,
175 reveal potential leverage points, and help foster coordinated solutions for international supply chains
176 that span multiple stakeholders across the private-public interface (12, 15). If supporting companies
177 make good on their commitments, this would in turn help governments make significant progress
178 towards their own commitments to eliminate deforestation, and may push the sustainability bar
179 higher for smaller or newer actors in the European market. Within our analyses, the two countries
180 with the greatest overall impacts – Brazil and China – have not yet signed key declarations at national
181 level (although note that Mato Grosso, an important soy producing state within the Cerrado, has

182 committed to its Produce, Conserve and Include Strategy, which aims to reduce Cerrado deforestation
183 by 95% and to restore habitat 25).

184 Attributing impacts to the country of first import can both severely underestimate (e.g. Denmark and
185 Norway), or overestimate (e.g. the Netherlands) impacts attributed to a country's final consumption.
186 However, in the same way that identifying key traders operating within the supply chain can help
187 identify important opportunities for intervention, so too can identifying the most significant hubs for
188 trade. The Netherlands is the largest importer of soy in Europe and the second largest exporter of
189 agricultural products in the world (26). It also processes approximately 25% of its soy imports to
190 produce animal feed (26). These factors underlie its central role in the global soy value chain, and its
191 founding role in the Amsterdam Declaration. The Netherlands could continue to exert
192 disproportionate influence on trading companies and buyers as a convening power and focal point of
193 private-public dialogue and partnerships (e.g. Dutch Soy Coalition, Dutch Soy Working Group and the
194 Dutch Soy Platform Initiative)(24, 26). The Dutch government has also provided support to processors
195 and buyers that invest in certification (Soy Fast Track Fund), as well as to farmers to enable them to
196 produce more sustainable soy (Farmer Support Programme)(26). In addition, governments have an
197 important convening and financing role to play in establishing sustainable finance – including provision
198 of credit lines to farmers that adhere to higher sustainability criteria, or support to scale up innovative
199 solutions to sustainability challenges (e.g. 27, 28). Our estimates of the impacts of final consumption
200 highlight the substantial responsibilities too of other EU countries, such as Spain, which is not
201 currently signatory to the declaration but could be a focal point for targeted political influence by
202 existing signatories (Table 1).

203
204 While the Netherlands may hold some influence because its large trade volumes, its diverse portfolio
205 of traders could make policy processes more complex and contested. In contrast to other AD countries
206 a large proportion of soy exported to (and through) the Netherlands is from traders without zero-
207 deforestation commitments. Hence, even if those with existing commitments delivered on them, this
208 would capture just half of the Cerrado soy traded through the Netherlands (Fig. 3; SI Appendix 1, Table
209 S3). Working with countries that directly import substantially smaller volumes, such as the UK, France
210 and Germany, may help the Netherlands government to encourage currently uncommitted yet major
211 traders such as Caramuru or Granol to sign up to targets to eliminate deforestation from their supply
212 chains.

213
214 There are several sources of uncertainty within the models presented – for example in modelling land
215 cover, estimating biodiversity loss, modelling trade, and year-to-year variability of supply chains. The
216 Trase SEI-PCS model of subnational production and export is built from key government statistics and
217 data that are compiled to calculate agricultural productivity and to collect tax revenues (29). This
218 allows considerable confidence in this aspect of the modelling. The IOTA model employed in the
219 analysis is one of several MRIO models that are available globally, all of which will provide somewhat
220 different quantitative results due to differences in their construction (30). Our results are illustrative of
221 the impacts that different countries might have; highlighting the heterogeneity that is expected across
222 the trade-system. Use of such information in risk-assessment or supply chain decision making should
223 consider the assumptions made and associated limitations of the modelling approaches. More
224 targeted analysis (e.g. of particular supply chains looking at specific priority species) would benefit
225 from further sensitivity analyses to explore how changes in assumptions might affect conclusions. We
226 use 2011 trade data in our analyses that provide a snapshot of a dynamic system – particularly in the
227 most active frontiers of agricultural expansion. Any intervention should be based on multi-temporal
228 analyses of spatial patterns and trends, as well as iterative engagement with stakeholders to ensure

229 their accuracy and relevance. However, because of the investments in infrastructure (such as silos and
230 crushing facilities) and knowledge, and interdependencies between actors, we expect traders to stay
231 relatively connected to particular production locations over a 3-5 year span, with more significant
232 changes occurring over longer periods (20, 31, 32; see preliminary analyses in SI Appendix 2, Figs. S3,
233 S4). Understanding how the data available within our framework might be used to help determine
234 accountability for impacts occurring across a dynamic trading landscape, where impacts can occur
235 several years prior to trading activities, deserves additional research focus.

236 Conclusion

237 Currently, many sustainability commitments are little more than statements of intent and a
238 recognition that things need to change (12, 15). Meeting these commitments requires collective action
239 to be scaled-up through multi-stakeholder partnerships, landscape-scale approaches and public-
240 private initiatives (12). Identifying links between the intensification and expansion of agricultural
241 commodity production and the demand that drives it is a vital first step to engage the political and
242 private actors with greatest responsibility and influence. We provide a highly flexible framework for
243 delivering a range of practical insights to stakeholders in international commodity supply chains.
244 Businesses can use this information to understand risks in their supply chains, while civil society,
245 consumers and shareholders can use it to hold governments and businesses to account on their
246 commitments. Investors too are increasingly interested in understanding investment-linked
247 environmental and social risks (33), and this will likely increase as transparency initiatives more
248 precisely link the environmental damage caused by commodity production to hitherto-opaque
249 financial systems underpinning it (34).

250 The high spatial resolution of our trade model tracking production and subnational flows is a major
251 advance for two reasons: first, in enhancing the credibility and spatial representation of estimates of
252 environmental impact and, second, in transforming our ability to devise and implement responses. For
253 example, campaigners can use impacts on flagship species to galvanise support from consumer groups
254 and to promote responsible consumption across supply chain actors. Higher resolution models allow
255 us to develop land-use management strategies to target particular areas for improving yields, setting
256 aside areas for protection in expansion landscapes, or expanding production into degraded land
257 according to the level of endemicity or of historical impacts on biodiversity. More generally, the spatial
258 resolution demonstrated here allows the development of more credible estimates for a suite of
259 indicators of environmental and social impacts. This species-level metric complements, rather than
260 replaces, other measures of biodiversity loss based on loss of ecosystems (such as loss of Cerrado, or
261 deforestation)(e.g. 35, 36). Taken together these provide a more complete picture of how the trade in
262 a commodity such as soy drives both immediate and longer-term losses and has impacts at scales from
263 the very local to global. It also allows assessment of complementarity or trade-offs between, for
264 example, protecting forests versus endemic species.

265 Our approach is applicable to a wide range of globally traded agricultural commodities. However, to
266 ‘catalyse a race to the top’ (14), actors must also be supported by mechanisms that allow and
267 recognise iterative improvements. Without such mechanisms, shedding light on sustainability
268 problems within particular supply chains may cause actors to shift to different production regions,
269 rather than improving practices in vulnerable areas, or start supplying consuming regions without
270 commitments to eliminate deforestation or where consumer pressure is currently lower (12, 15).
271 Anticipating such ‘leakage’ between areas, countries and indeed different commodity crops is vital. In
272 this context our ability to document country-trader relationships is likely to play an important role.
273 Many of the biggest traders source from multiple producer countries, sell their goods globally, and
274 have activities that span several commodities (37). This global reach may allow successful

275 sustainability initiatives to quickly scale up to other regions and commodities. By enabling monitoring
276 of shifts of traders between markets our framework can also help minimise leakage by ensuring that
277 sustainability commitments apply across companies' operations. Moreover, because of the dominant
278 role that a relatively few traders hold as a nexus of global commodity flows (38, 39), pressure from
279 major economies - such as the AD countries - to improve environmental standards could drive
280 improvements to the sustainability of supply chains to other consuming regions.

281 **Methods**

282 We compile and integrate existing data sources, linking complementary approaches to derive new
283 information on consumption patterns driving species declines, and shedding light on the supply chains
284 involved (SI Appendix 3, Fig. S5). Existing multiregional input-output models (MRIOs) use data on inter-
285 sectoral financial transactions to represent full global trade and consumption, but sacrifice
286 commodity-specific detail and spatial resolution. Conversely, material flow analyses – descriptions of
287 the physical movement of commodities – can be used to track production and trade of individual
288 commodities, but generally capture only a portion of the supply chain (40). We therefore develop a
289 hybridised MRIO for soy trade that combines traditional input-output analyses with highly detailed
290 subnational material flow data from the Spatially Explicit Information on Production to Consumption
291 Systems (SEI-PCS) model underpinning the Trase platform (36, 41) (SI Appendix 3). We use these to
292 tease out the activities of producers, traders, and consumers. We link the models to estimates of
293 species-by-species losses of suitable habitat to derive a measure of biodiversity impact that accounts
294 for species-specific differences in range sizes, sensitivities to land-use change and historical habitat
295 loss (17)(SI Appendix 3, Fig. S5). We focus on the impacts of soy production in 2000-10 using habitat
296 loss data for 2000-10 and soy trade data for 2011. We chose this allocation period (i.e. attributing
297 2000-2010 losses to 2011) because it can take several years from initial clearing of land to eventual
298 harvesting and selling soy.

299 **Acknowledgements**

392

393 Figure Legends

394

395 **Fig. 1.** (a) Impact of Cerrado-grown soy on endemic biodiversity (as a percentage of global impacts of soy in the Cerrado), plotted against
396 embedded consumption of Cerrado-sourced soy (as a percentage of global Cerrado-sourced soy consumption) for the seven Amsterdam
397 Declaration (AD) countries, Brazil, the countries of the European Union (EU28), China (including Hong Kong and Taiwan), India, North
398 America, South America, and the Rest of the World (RoW). Grey line indicates mean global impact per unit of soy consumption. (b) Spatial
399 pattern of our endemic biodiversity loss index within the Cerrado during the period 2000–2010; (c) Difference (tonnes) between production for
400 domestic consumption (all Brazil) and Chinese consumption. Negative values (blue) are municipalities where production for Chinese
401 consumption exceeds production for Brazil. Positive values (orange/red) are municipalities where production for Brazilian consumption
402 exceeds production for China; (d) Comparison of the relative soy-attributed biodiversity impact that is directly imported to AD countries and
403 impact that is attributed to final consumption within those countries (i.e. the latter accounts for both re-exports and embedded consumption);
404 (e) Sectoral and country-wise differences for AD countries showing relative impact of three key soy-linked sectors as a percentage of each
405 country's consumption of soy across all sectors combined. Value above bar indicates the relative importance of each country to global
406 biodiversity impacts of Cerrado-sourced soy.

407 **Fig. 2.** Chord diagrams showing impacts on likelihood of persistence due to soy expansion between 2000 and 2010 for two charismatic species
408 (top) and for all endemics (bottom left). Losses are calculated for each municipality according to the total embedded flows of soy and then
409 aggregated to state-level for visualisation. Chords show the flow from states on the left hand side (BA=Bahia, dark blue; DF=Distrito Federal,
410 grey; GO=Goiás, red; MA=Maranhão, cyan; MG=Minas Gerais, light green; MS=Mato Grosso do Sul, purple; MT=Mato Grosso, dark green;
411 PI=Piauí, pink; PR=Paraná, dark olive green; RO=Rondônia, brown; SP=São Paulo, dark grey; TO=Tocantins, gold) through to the country or
412 region of final consumption on the right hand side (Brazil; South America; North America, European Union; India; China; Rest of World). The
413 proportion of remaining suitable habitat within the Cerrado for the two species (bottom right) and the mean for all endemic species. Light
414 grey: suitable habitat lost from pre-industrial era to year 2000; red: losses during the 2000 to 2010 study period (as represented in the chord
415 diagrams); medium grey: losses between 2010 and 2014; dark grey: remaining suitable habitat in 2014.

416

417 **Fig. 3.** Alignment of government commitments with sustainability goals of key traders. Chord diagram representing direct soy trade from the
418 Brazilian Cerrado to the seven countries of the Amsterdam Declaration from the largest traders in 2011 (companies shown were among the
419 top 3 traders in 2011 for at least one of the countries; companies trading smaller volumes are aggregated and shaded grey). Green shaded
420 chords indicate exports via companies with zero-deforestation commitments; orange/brown shades indicate no such commitment (data from
421 company websites as of Dec 2018).

422

423

*Table 1.*The countries whose embedded consumption of soy from the Cerrado in 2011 is estimated to have the greatest impact on endemic biodiversity (domestic plus top ten international consuming countries). Relative impact per unit mass of soy consumed from 0 (no impact) to 1 (greatest observed impact across all consuming regions). We highlight country commitments to the New York Declaration on Forests (NYDF) and Amsterdam Declaration (AD). Asterisks indicate local, but not national, government signatories to NYDF. See also SI Appendix 1, Table S1.

Consuming region	Relative impact	Relative Impact/mass consumed	Commitment
Brazil	44.9%	0.87	*
China	22.0%	0.38	
Japan	2.9%	0.52	NYDF
Germany	2.7%	0.49	NYDF/AD
Spain	2.5%	0.61	*
Thailand	2.3%	0.55	
United States of America	1.9%	0.36	NYDF
United Kingdom	1.8%	0.46	NYDF/AD
France	1.8%	0.33	NYDF/AD
Netherlands	1.4%	0.60	NYDF/AD
Italy	1.2%	0.87	AD
